The character of the languages of this family, especially as instanced by its most important member, the Chinese, has been pretty fully set forth in the general discussions above. They are languages of roots: that is to say, there is not demonstrable in any of their words a formative part, limiting the word, along with others similarly characterized, to a certain office or set of offices in the formation of the sentence. That the words are ultimate roots, come down from the first period of language-making, we have no reason whatever to believe; and they may possibly have passed through processes of growth which equipped them with some scanty supply of forms; but no evidence to that effect has yet been produced. The indications relied on to show an earlier polysyllabism in the family (though already in Chinese reduced to monosyllabism before the earliest historical appearance of the language, some 4000 years ago) are the comparatively recent loss of certain final mutes in Chinese words, and the presence on a considerable scale in Tibetan spelling of added initial and final consonants, now silent in the literary dialect, but claimed to be still uttered in some parts of the country. If the theory connecting these phenomena be established, the Tibetan will approve itself to be by far the most primitive of the dialects of the family, furnishing the key to the history of the rest.

For further details respecting the various tongues of the monosyllabic family, the articles on the different divisions of its territory (BURMA; CHINA; SIAM; TIBET, &c.) may be consulted. The languages all alike show an addition to the resources of distinction possessed by languages in general, in the use of tones: that is to say, words of which the alphabetic elements are the same differ in meaning according as they are uttered in a higher or a lower tone, with the rising or the falling inflexion, and so on. By this means, for example, the monosyllabic elements of the literary Chinese, numbering but 500 as we should write them, are raised to the number of about 1500 words.

5. *Ural-Altaic* (*Scythian, Turanian*) *Family.*—China and Tibet are bordered on the north and west by the eastern branches of another immense family, which stretches through central and northern Asia into Europe, overlapping the European border in Turkey, and reaching across it in Russia and Scandinavia to the very shore of the Atlantic. Usage has not so definitely determined as in the case of most other families by what name it shall be called; Turanian is perhaps the commonest appellation, but also the most objectionable. Five principal branches are generally reckoned as composing the family. The two easternmost are the Tungusian, with the Manchu for its principal division, and the Mongol (see MONGOLS).

preponderance. Thus, there is left in French only an insignificant trace of the Celtic dialects of the predominant race-constituent of the French people; French is the speech of the Latin conquerors of Gaul, mixed perceptibly with that of its later Frankish conquerors; it was adopted in its integrity by the Norse conquerors of a part of the land, then brought into Britain by the same Norsemen in the course of their further conquests, this time only as an element of mixture, and thence carried with English speech to America, to be the language of a still further mixed community. Almost every possible phase of language-mixture is traceable in the history of the abundant words of Latin origin used by American negroes. What events of this character took place in prehistoric time we shall never be able to tell. If any one chooses to assert the possibility that even the completely isolated dialect of the little Basque community may have been derived by the Iberian race from an intrusive minority as small as that which made the Celts of Gaul speakers of Latin, we should have to admit it as a possibility—yet without detriment to the value of the dialect as indicating the isolated race-position of its speakers. In strictness, language is never a proof of race, either in an individual or in a community; it is only a probable indication of race, in the absence of more authoritative opposing indications; it is one evidence, to be combined with others, in the approach towards a solution of the confessedly insoluble problems of human history. But we must notice, as a most important circumstance, that its degree of probability is greatest where its aid is most needed, in prehistoric periods and among uncultivated races; since it is mainly civilization that gives to language a propagative force disproportionate to the number of its speakers. On the whole, the contributions of language to ethnology are practically far greater in amount and more distinct than those derived from any other source.

Classification.

The genetical classification of languages, then, is to be taken for just what it attempts to be, and no more: primarily as a classification of languages only; but secondarily as casting light, in varying manner and degree, on movements of community, which in their turn depend more or less upon movements of races. It is what the fates of men have left to represent the tongues of men—a record imperfect even to fragmentariness. Many a family once as important as some of those here set down has perhaps been wiped out of existence, or is left only in an inconspicuous fragment; one and another has perhaps been extended far beyond the limits of the race that shaped it—which, we can never tell to our satisfaction.

1. *Indo-European (Indo-Germanic) Family.*—To this family belongs incontestably the first place, and for many reasons: the historical position of the peoples speaking its dialects, who have now long been the leaders in the world's history; the abundance and variety and merit of its literatures, ancient and modern, which, especially the modern, are wholly unapproached by those of any other division of mankind; the period covered by its records; and, most of all, the great variety and richness of its development. These advantages make of it an illustration of the history of human speech with which no other family can bear a moment's comparison as to value, however important various other families may be in their bearing on one and another point or department of history, and however necessary the combination of the testimony of all to a solution of the problems involved in speech. These advantages have made Indo-European language the training-ground of comparative philology, and its study will always remain the leading branch of that science. Many matters of importance in its history have been brought up and used as illustrations in the preceding discussion; but as its constitution and ascertained development call for a fuller and more systematic exposition than they have found here, a special section is devoted to the subject (see Part II. below; also INDO-EUROPEAN LANGUAGE).

2. *Semitic Family.*—This family also is beyond all question the second in importance, on account of the part which its peoples (Hebrews, Phoenicians, Assyrians, Syrians, Arabs, Abyssinians, &c.) have played in history, and of the rank of its literatures. For a special treatment of it see SEMITIC LANGUAGES. Some of the peculiarities of the language have been alluded to above; in the monotony and rigidity of its triliteral roots, and in the extended use which it makes of internal vowel-change ("inflexion" in the special sense of that term) for the purposes of grammatical distinction, it is more peculiar and unlike all the other known families of language than these are unlike one another. There are, and perhaps will always be, those to whom the peculiarities just mentioned will seem original; but if the views of language and its history taken above are in the main true, then that opinion is untenable; Semitic language must have grown into its present forms out of beginnings accordant in kind, if not identical in substance, with those of other families; and the only question remaining to be solved is, through what processes and under what governing tendencies Semitic speech should have arrived at its present state. And with this solution is most obviously and incontestably bound up that of the other interesting and much discussed question, whether the Semitic family can be shown to be related with other families, especially with the Indo-European. To some the possession in common of grammatical gender, or of the classification of objects in general as masculine and feminine, is of itself enough to prove such relationship; but, though the fact is a striking one, and of no small importance as an indication, this degree of value can by no means be attributed to it in the present state of our knowledge—any more than to any other single item of structure among the infinite variety of such, distributed among the multitude of human tongues. Many others compare the Semitic and Indo-European "roots" with one another, and believe themselves to find there numerous indications of identity of material and signification; but these also must pass for insufficient, until it shall prove possible by their aid to work out an acceptable theory of how Semitic structure should have grown out of such radical elements as underlie Indo-European structure, or out of the accordant initial products of a structural growth that afterwards diverged into two so discordant forms. To show that, both the material and the method have been hitherto wanting, and any confident decision is at least premature; but present probabilities are strongly against the solubility of the question. While many general considerations favour the ultimate unity of these two great civilized and civilizing white races of neighbouring homes, and no discordance of speech (as was shown above) can ever be made to prove their diversity of origin, it seems in a high degree unlikely that the evidence of speech will ever be made to prove them one.

3. *Hamitic Family.*—The prominent importance of this family (see HAMITIC LANGUAGES) is due to a single one of its members, the Egyptian. It occupies the north-eastern corner of Africa, with the border-lands of that continent stretching westward along the whole shore of the Mediterranean, and southward to beyond the equator. It falls into three principal divisions: (1) the ancient Egyptian, with its descendant, the more modern Coptic (itself now for some centuries extinct; see EGYPT, COPTS); (2) the Libyan or Berber languages of northern Africa; (3) the Ethiopic languages of eastern Africa. Its situation thus plainly suggests the theory of its intrusion from Asia, across the isthmus of Suez, and its gradual spread from that point; and the theory is strongly favoured by the physical character of the Hamites, and the historical position, especially of the Egyptians, so strikingly different from that of the African races in general. Linguistic evidences of the relationship of Hamite with Semite have also been sought, and by many believed to be found; but the maintenance of the two families in their separateness is an indication that those evidences have not yet been accepted as satisfactory; and such is indeed the case. The Egyptian is a language of extreme simplicity of structure, almost of no structure at all. Its radical words are partly monosyllabic, partly of more than one syllable, but not in the latter case any more than in the former showing traceable signs of extension by formative processes from simpler

Etruscan language of northern central Italy, which long ago became extinct, in consequence of the conquest and absorption of Etruria by Rome, but which still exists in numerous brief inscriptions (see ETRURIA). Many attempts have been made to connect the language with other families, and it has even quite recently been pronounced Aryan or Indo-European, of the Italican branch, by scholars of high rank. But its supposed Indo-European relationship was at once shown to be erroneous when, in 1892, a small book which had been used to pack a mummy was discovered in the museum at Agram, and published. The probability of relationship with the ancient Lydian, as was the opinion held in ancient times, has been increased by recent research, and is likely soon to be verified or disproved by the discovery of Lydian records.

In order to complete this review of the languages of the Old World it only remains to notice those of Africa which have not been already mentioned. They are grouped under two heads: the languages of the south and those of the centre of the continent.

11. *South African or Bantu Family.*—This is a very extensive and distinctly marked family (see BANTU LANGUAGES), occupying (except the Hottentot and Bushman territory) the whole southern peninsula of the continent from some degrees north of the equator. It is held apart from all other known families of language by a single prominent characteristic—the extent to which it makes use of prefixes instead of suffixes as the apparatus of grammatical distinction; its inflexion, both declensional and conjugational, is by appended elements which precede the stem or root. The most conspicuous part of this is the variety of prefixes, different in singular and plural, by which the various classes or genders (not founded on sex; the ground of classification is generally obscure) of nouns are distinguished; these then reappear in the other members of the sentence, as adjectives and verbs and pronouns, which are determined by the noun, thus producing an alliterative concord that runs through the sentence. The pronominal determinants of the verb, both subject and object, also come before it; but the determinants of mode of action, as causative, &c., are mostly suffixed. The language in general is rich in the means of formal distinction. Those dialects which border on the Hottentots have, apparently by derivation from the latter, the clicks or clucking-sounds which form a conspicuous part of the Hottentot spoken alphabet.

12. *Central African Languages.*—The remaining languages of Africa form a broad band across the centre of the continent, between the Bantu on the south and the Hamitic on the east and north. The Bantu group, extending from north of the equator to the Cape of Good Hope, with a vast variety of dialects, is the most important of all African languages. To it belongs Swahili, the language of Zanzibar, only less valuable as a means of communication and trade than the Haussa of the Sudan, the most important of the dialects under the influence of the Hamitic languages. The African languages are by no means to be called a family, but rather a great mass of dialects, numbering by hundreds, of varying structure, as to the relations of which there is great discordance of opinion even among the most recent and competent authorities. It is no place here to enter into the vexed questions of African linguistics, or even to report the varying views upon the subject; that would require a space wholly disproportioned to the importance of African speech in the general sum of human language. There is no small variety of physical type as well as of speech in the central belt; and, partly upon the evidence of lighter tint and apparently higher endowment, certain races are set off and made a separate division of; such is the Nuba-Fulah division of F. Müller, rejected by Lepsius. The latter regarded all the varieties of physical and linguistic character in the central belt as due to mixture between pure Africans of the south and Hamites of the north and east; but this is at present an hypothesis only, and a very improbable one, since it implies modes and results of mixture to which no analogies are quotable from languages whose history is known; nor does it appear at all probable that the collision of two races and types of speech should produce such an immense and diverse body of transitional types. It is far from impossible that the present prominence of the South African or Bantu family may be secondary, due to the great expansion under favouring circumstances of a race once having no more importance than belongs now to many of the Central African races, and speaking a tongue which differed from theirs only as theirs differed from one another. None of the Central African languages is a prefix-language in the same degree as the Bantu, and in many of them prefixes play no greater part than in the world's languages in general; others show special forms or traces of the prefix structure; and some have features of an extraordinary character, hardly to be paralleled elsewhere. One group in the east (Oigob, &c.) has a gender distinction, involving that of sex, but really founded on relative power and dignity: things disparaged, including women, are put in one class; things extolled, including men, are put in the other. This is perhaps the most significant hint anywhere to be found of how a gender-distinction like that in our own Indo-European languages, which we usually regard as being essentially a distinction of sex, while in fact it only includes such, may have arisen. Common among the African languages, as among many other families, especially the American, is a generic distinction between animate beings and inanimate things.

13. *American Languages.*—With these the case is closely the same as with the Central African languages: there is an immense number of dialects, of greatly varied structure (see INDIANS, NORTH AMERICAN). Even among neighbouring families like the Algonquin, Iroquois and Dakota, whose agreement in style of structure (polysynthetic), taken in connexion with the accordant race-type of their speakers, forbids us to regard them as ultimately different, no material correspondence, agreement in words and meanings, is to be traced; and there are in America all the degrees of polysynthetism, down to the lowest, and even to its entire absence. Such being the case, it ought to be evident to every one accustomed to deal with this class of subjects that all attempts to connect American languages as a body with languages of the Old World are and must be fruitless.

Literature.—Many of the theoretic points discussed above are treated by the writer with more fullness in his *Language and the Study of Language* (1867) and *Life and Growth of Language* (1875). Other English works to consult are M. Müller's *Lectures on the Science of Language*; Farrar's *Chapters on Language*; Wedgwood's *Origin of Language* (all more or less antiquated); Sayce's *Principles of Philology* and *Introduction to the Science of Language*, &c.; Sweet, *The History of Language* (1900). In German, see Paul's *Principien der Sprachgeschichte* (Halle, 1880); Delbrück's *Einleitung in das Sprachstudium* (Leipzig, 1880; 4th ed., 1909; 5th ed., 1910; there is also an English version); Brugmann and Delbrück's *Grundriss der vergleichenden Grammatik der indogermanischen Sprachen* (1886–1900; a second edition of the first volume was published in 1897, two parts of vol. ii., including the stem-formation and declension of the noun and pronoun appeared in 1906 and 1909); also the works of W. von Humboldt and of H. Steinthal, the most important of whose linguistic works, *Charakteristik der hauptsächlichsten Typen des Sprachbaues* (1861), was recast and brought up to date under the same title by F. Misteli (1893). See also handy summaries covering the same ground, but without bibliography, in F. N. Finck's *Die Sprachstämme des Erdkreises* (1909) and *Die Haupttypen des Sprachbaus* (1910). Many of the languages of India and Farther India have been treated in the *Linguistic Survey of India*, edited by Dr G. E. Grierson (a government publication still in progress). A short popular account of the subject is given in Porzczinski's *Einleitung in die Sprachwissenschaft* (1910), a German translation of a Russian original. The Bantu languages have been treated by Blaek, Torrand, and most recently by Meinhof, whose *Lautlehre der Bantu Sprachen* (1910) is the most complete handling of the subject. As to the classification and relationships of languages, see Hovelacque's *La Linguistique* (Paris, 1876) and F. Müller's *Grundriss der Sprachwissenschaft* (Vienna, 3 vols.; a fourth was left incomplete at the author's

preponderance. Thus, there is left in French only an insignificant trace of the Celtic dialects of the predominant race-constituent of the French people; French is the speech of the Latin conquerors of Gaul, mixed perceptibly with that of its later Frankish conquerors; it was adopted in its integrity by the Norse conquerors of a part of the land, then brought into Britain by the same Norsemen in the course of their further conquests, this time only as an element of mixture, and thence carried with English speech to America, to be the language of a still further mixed community. Almost every possible phase of language-mixture is traceable in the history of the abundant words of Latin origin used by American negroes. What events of this character took place in prehistoric time we shall never be able to tell. If any one chooses to assert the possibility that even the completely isolated dialect of the little Basque community may have been derived by the Iberian race from an intrusive minority as small as that which made the Celts of Gaul speakers of Latin, we should have to admit it as a possibility—yet without detriment to the value of the dialect as indicating the isolated race-position of its speakers. But we must notice, as a most important circumstance, that its degree of probability is greatest where its aid is most needed, in prehistoric periods and among uncultivated races; since it is mainly civilization that gives to language a propagative force disproportionate to the number of its speakers. On the whole, the contributions of language to ethnology are practically far greater in amount and more distinct than those derived from any other source.

Classification.

The genetical classification of languages, then, is to be taken for just what it attempts to be, and no more: primarily as a classification of languages only; but secondarily as casting light, in varying manner and degree, on movements of community, which in their turn depend more or less upon movements of races. It is what the fates of men have left to represent the tongues of men —a record imperfect even to fragmentariness. Many a family once as important as some of those here set down has perhaps been wiped out of existence, or is left only in an inconspicuous fragment; one and another has perhaps been extended far beyond the limits of the race that shaped it—which, we can never tell to our satisfaction.

1. *Indo-European* (*Indo-Germanic*) *Family.*—To this family belongs incontestably the first place, and for many reasons: the historical position of the peoples speaking its dialects, who have now long been the leaders in the world's history; the abundance and variety and merit of its literatures, ancient and modern, which, especially the modern, are wholly unapproached by those of any other division of mankind; the period covered by its records; and, most of all, the great variety and richness of its development. These advantages make of it an illustration of the history of human speech with which no other family can bear a moment's comparison as to value, however important various other families may be in their bearing on one and another point or department of history, and however necessary the combination of the testimony of all to a solution of the problems involved in speech. These advantages have made Indo-European language the training-ground of comparative philology, and its study will always remain the leading branch of that science. Many matters of importance in its history have been brought up and used as illustrations in the preceding discussion; but as its constitution and ascertained development call for a fuller and more systematic exposition than they have found here, a special section is devoted to the subject (see Part II. below; also INDO-EUROPEAN LANGUAGE).

2. *Semitic Family.*—This family also is beyond all question the second in importance, on account of the part which its peoples (Hebrews, Phoenicians, Assyrians, Syrians, Arabs, Abyssinians, &c.) have played in history, and of the rank of its literatures. For a special treatment of it see SEMITIC LANGUAGES. Some of the peculiarities of the language have been alluded to above; in the monotony and rigidity of its triliteral roots, and in the extended use which it makes of internal vowel-change ("inflexion" in the special sense of that term) for the purposes of grammatical distinction, it is more peculiar and unlike all the other known families of language than these are unlike one another. There are, and perhaps will always be, those to whom the peculiarities just mentioned will seem original; but if the views of language and its history taken above are in the main true, then that opinion is untenable; Semitic language must have grown into its present forms out of beginnings accordant in kind, if not identical in substance, with those of other families; and the only question remaining to be solved is, through what processes and under what governing tendencies Semitic speech should have arrived at its present state. And with this solution is most obviously and incontestably bound up that of the other interesting and much discussed question, whether the Semitic family can be shown to be related with other families, especially with the Indo-European. To some the possession in common of grammatical gender, or of the classification of objects in general as masculine and feminine, is of itself enough to prove such relationship; but, though the fact is a striking one, and of no small importance as an indication, this degree of value can by no means be attributed to it in the present state of our knowledge—any more than to any other single item of structure among the infinite variety of such, distributed among the multitude of human tongues. Many others compare the Semitic and Indo-European "roots" with one another, and believe themselves to find there numerous indications of identity of material and signification; but these also must pass for insufficient, until it shall prove possible by their aid to work out an acceptable theory of how Semitic structure should have grown out of such radical elements as underlie Indo-European structure, or out of the accordant initial products of a structural growth that afterwards diverged into two so discordant forms. To show that, both the material and the method have been hitherto wanting, and any confident decision is at least premature; but present probabilities are strongly against the solubility of the question. While many general considerations favour the ultimate unity of these two great civilized and civilizing white races of neighbouring homes, and no discordance of speech (as was shown above) can ever be made to prove their diversity of origin, it seems in a high degree unlikely that the evidence of speech will ever be made to prove them one.

3. *Hamitic Family.*—The prominent importance of this family (see HAMITIC LANGUAGES) is due to a single one of its members, the Egyptian. It occupies the north-eastern corner of Africa, with the border-lands of that continent stretching westward along the whole shore of the Mediterranean, and southward to beyond the equator. It falls into three principal divisions: (1) the ancient Egyptian, with its descendant, the more modern Coptic (itself now for some centuries extinct; see EGYPT, COPTS); (2) the Libyan or Berber languages of northern Africa; (3) the Ethiopic languages of eastern Africa. Its situation thus plainly suggests the theory of its intrusion from Asia, across the isthmus of Suez, and its gradual spread from that point; and the theory is strongly favoured by the physical character of the Hamites, and the historical position, especially of the Egyptians, so strikingly different from that of the African races in general. Linguistic evidences of the relationship of Hamite with Semite have also been sought, and by many believed to be found; but the maintenance of the two families in their separateness is an indication that those evidences have not yet been accepted as satisfactory; and such is indeed the case. The Egyptian is a language of extreme simplicity of structure, almost of no structure at all. Its radical words are partly monosyllabic, partly of more than one syllable, but not in the latter case any more than in the former showing traceable signs of extension by formative processes from simpler

the elucidation of Latin and the cognate Italic idioms. In his *Compendium* Schleicher undertook and solved the difficult task of sifting down the countless details amassed since the days of Bopp and Grimm, and thus making the individual languages stand out clearly on their common background, while Bopp's attention had been especially occupied with what was common to all Indo-European tongues. There are two prominent features which characterize this part of Schleicher's work—his assumption and partial reconstruction of a prehistoric parent speech, from which the separate Indo-European languages were supposed to have sprung, and the establishment of a long series of phonetic laws, regulating the changes by which that development of the individual idioms had taken place. On Schleicher's views of and contributions towards general comparative philology (which he erroneously proposed to consider as a branch of natural science) we need not enter here. (See *Evolution and the Science of Language in Darwin and Modern Science*, 1909, pp. 526 sqq.)

For some time after Schleicher's premature death (in 1868) Indo-European philology continued in paths indicated by him and Curtius, with the exception, perhaps, of the school founded by Benfey, who had always stood on independent ground. The difference between the two schools, however, was less strikingly marked in their writings, because it chiefly concerns general views of language and the Indo-European languages in particular, although the characteristic task of the period alluded to was that of working out the more minute details of comparison; but behind all this the general interest still clung to Bopp's old glottogonic problems. In 1876, however, a new movement, inspired in the first instance by the works of W. D. Whitney, began, and a younger school of linguists has sprung up who are united in their opposition to many theories of the older generation, yet often differ materially both with regard to method and the solution of individual problems. In its present state this younger school (often branded with the name of Neo-Grammarians, "Junggrammatiker," by its opponents real and imaginary) is marked by certain distinct tendencies. In the first place, they are inclined more or less, and the older members of the school perhaps more than the younger, to abandon glottogonic problems as insoluble, if not for ever, yet for the present and with the scanty means that Indo-European philology alone can furnish for this purpose. In this they are in opposition to the whole of the older school. In the second place, they object to the use of all misleading metaphorical comparisons of processes in the history of language with processes of organic development—comparisons used at all times, but especially cherished by Schleicher. In the third place—and this has been of the greatest practical importance—they hold that our general views of language and our methods of comparison should be formed after a careful study of the living languages, because these alone are fully controllable in every minute detail, and can therefore alone give us a clear insight into the working of the different motive forces which shape and modify language, and that the history of earlier periods of language, consequently, can only be duly illustrated by tracing out the share which each of these forces has had in every individual case of change. Of these forces two are found to be especially prominent—phonetic variation and formation by analogy. They generally work in turns and often in opposition to one another, the former frequently tending to differentiation of earlier unities, the latter to abolition of earlier differences, especially to restoration of conformity disturbed by phonetic change. There are, however, other important differences in the action of the two forces. Phonetic change affects exclusively the pronunciation of a language by substituting one sound or sound-group for another. From this simple fact it is self-evident that phonetic changes as such admit of no exceptions. Pronunciation—that is, the use of certain sounds in certain combinations—is perfectly unconscious in natural unstudied speech, and every speaker or generation of speakers has only one way of utterance for individual sounds or their combinations. If, therefore, a given sound was once changed into another under given circumstances, the new sound must necessarily and unconsciously replace its predecessor in every word that falls under the same rules, because the older sound ceases to be practised and therefore disappears from the language. Thus, for instance, the sound of the short so-called Italian *a* in English has become exchanged for the peculiarly English sound in *man*, *hat*, &c., which is so exclusively used and practised now by English speakers that they feel great difficulty in pronouncing the Italian sound, which at an earlier period was almost as frequent in English as in any other language that has preserved the Italian sound up to the present day. Again, the sound of the so-called long English *a* in *make*, *paper*, &c., although once a monophthong, is now pronounced as a diphthong, combining the sounds of the English short *e* and *i*, and no trace of the old monophthong is left, except where it was followed by *r*, as in *hare*, *mare* (also *air*, *their*, *where*, &c.), where the *a* has a broader sound somewhat approaching that of the short *a* in *hat*. This last instance may at the same time serve to illustrate the restrictions made above as to sounds changing their pronunciation in certain groups or combinations, or under given circumstances only. We may learn from it that phonetic change need not always affect the same original sound in the same way in all its combinations, but that neighbouring sounds often influence the special direction in which the sound is modified. The different sounds of the English *a* in *make* and *hare* are both equivalents of the same Old English sound *ă* (= the Italian short *a*) in *macian*, *hara*. The latter sound has been split in two, but this process again has taken place with perfect regularity, the one sound appearing before *r*, the other before all other consonants. It is easy to see that the common practice of comprising the history of the Old English *a* in the one rule—that it was changed into the sound of the *ā* in *make* except when followed by an *r*—can only be defended on the practical ground that this rule is convenient to remember, because the words exhibiting the former change are more numerous than the instances of the latter; apart from this there is nothing to justify the assumption that one of these changes is the rule and the other the exception. The fact is, that we have two independent cases of change, which ought to be stated in two distinct and independent rules according to the different positions in which the original *ă* stood before the splitting began. It is also easy to observe that the variety of modifying influences may be much more manifold than in the present instance of *make* and *hare*, and that the number of special phonetic rules in such cases must be increased in proportion to the progress made in the investigation of the said modifying powers.

New Linguistic School.

In truth, however, the study of phonetic laws falls into several different stages, and the meaning attached to the phrase *phonetic law* has varied at each of these stages. Moreover, the sweeping nature of the original generalizations has become so hedged in and contracted by limitations that a recent writer has been compelled once more to formulate the question whether phonetic laws actually exist. It must be admitted in the first place that the word *law* has been ill chosen for use in this connexion. In phonetic laws there is no element which can be identified as coming under the definition of a law as propounded by a jurist like John Austin. There is no authority which enunciates the law, there is no penalty for the breach of it. But the philologists who first used the term were not thinking of law in its strict signification, but of its use in such metaphorical expressions as scientific laws, for, as already mentioned, Schleicher and his followers in the middle of the 19th century had taken a keen interest in the development of the natural sciences, and had to some extent assimilated their terminology to that employed in those sciences. It was, however, soon recognized that the laws of language and those of natural science were not really alike or akin. A scientific "law" is only a brief method of expressing the fact that universal experience shows that certain causes universally produce certain effects. In chemistry two atoms of

Phonetic Change.

hydrogen and one of oxygen will make water and they will make nothing else at any time or at any place the world over. Phonetic laws, however, do not hold true universally. They are often curiously limited in the area to which they apply. In ancient Greek, for example, the sound *-s-* between two vowels, which had been handed down from the original language whence Greek and the sister languages are derived, regularly disappears; in Latin, on the other hand, it changes into *-r-*; thus an original genitive of a neuter substantive we find represented in Greek by *γένε-ος*, a form which comparison with other languages shows to be traceable to an earlier **genes-os*, preceding the separation of the languages, while the same original stem with a different vowel in the ending appears in Latin as *gener-is*. Similarly an early **euso* appears in Greek as *εὔω*, in Latin as *uro*. This disappearance of original intervocalic *s* pervades all Greek dialects—the apparent exceptions come under the heading of analogical change; with a very few exceptions similarly explicable Latin intervocalic *s* has become *r*. But Latin was originally limited to a very small part even of Italy, and the next neighbours of the Latins on the east and south—the Sabines, Campanians and Samnites—retained this intervocalic *s* without changing it into *r*. On the other hand, the neighbours to the north-east—the Umbrians in and beyond the Apennines—shared in this rhotacism. Yet the Celts, who bordered on the Umbrians along the Po, and who spoke a language in many respects very closely akin to the dialects of Italy, in this regard agree rather with Greek than the Italic languages. In Latin, again, the period of action of the law which changed intervocalic *s* into *r* did not in all probability exceed the century from 450 B.C. to 350 B.C. So unlike, indeed, are phonetic laws to the laws of natural science in universality that an opponent of the dogma which declares that phonetic laws have no exceptions has compared them with the laws of fashion. The comparison is not so outrageous as it may seem at first sight. For in language there are two kinds of sound change, that which is unconscious, universal at a given time and within a given area, and, on the other hand, that which belongs only to a particular class or clique, deviates consciously from the pronunciation of the majority, is therefore not universal, and exercises no permanent influence on the language. The second kind of sound change corresponds exactly to the laws of fashion; it is in fact one of them. Such sound changes are the pronunciation of the English ending *-ing* as *-in'*, which was fashionable in the middle of the 19th century. This had, though probably without the knowledge of those who used it, an historical justification in the earlier forms from which most of the English words now ending in *-ing* are descended, and which survive in numerous local dialects. A similar conventional mispronunciation was the lisp affected by some would-be artistic persons at a somewhat later period. Belonging to an entirely different social stratum, and now equally obsolete, was the London pronunciation of the first half of the 19th century typified in Tony and Sam Weller's treatment of *v* and *w* in the *Pickwick Papers*. This, however, made a much nearer approach to being a genuine dialect peculiarity. It undoubtedly pervaded the pronunciation of the lower classes in London at one time; had it survived it might conceivably have spread over a wider and wider area until it embraced the whole population of England. A later change, that of the diphthong *ai* into *ei* (so that *day*, *daily* are pronounced *dy*, *dyly*), has spread from Essex and the East End of London over a large part of London and of the adjacent counties, and is still widening its range both geographically and socially. The history of these sound changes has not yet been investigated in detail with the thoroughness which it deserves.

There is, then, a part of sound change which is a matter of fashion and which is conscious. This sound change appears frequently in the pronunciation of individuals who have migrated from one part of a country to another. In many parts of Scotland, for example, the prepositions *with* and *of* appear in dialect only in the forms *wi'* and *o'*, which were originally the unaccented forms. In the conscious attempts to pronounce them as they appear in literary English, the educated Scotsman, if he remains in his native place, as a rule pronounces them as *with* (with the final sound unvoiced as it appears in the Scottish legal preposition *outwith*) and as *off*, the final sound here also being unvoiced. If he migrates to England or to Australia he will probably in course of time adopt the pronunciation with a voiced final sound. In the course of years habit will become second nature, and in this respect the speaker's pronunciation will become identical with that of his neighbours. It is clear, however, that changes of this nature cannot take place on a large scale. If a large number of persons migrate in a body and continue to live in close intercourse with one another and but little in contact with the outside world, changes such as take place in the pronunciation of the individual emigrant do not occur. There can be no imitation of alien sounds, for there are none; no greater effort to be intelligible is required, for the audience has not changed. Hence it has been often remarked that a population which history shows to have remained undisturbed for very long periods in the same geographical situation manifests but little change in its language. Thus in Arabia and Lithuania the population has remained practically unmixed in the same habitat for thousands of years, with the result that the languages spoken there remain at the present day the most archaic members of the linguistic families to which they respectively belong.

From what has been said it will be obvious that a phonetic law is only an observed uniformity in the treatment of a sound or a combination of sounds within a linguistic area at a given time. In the definition the term *linguistic area* is a very variable quantity. Thus it is a phonetic law that a sound of the original Indo-European language, the precise pronunciation of which cannot be determined, but which was at any rate a palatal sound ($\acute{k}$), appears in the Indo-European group (Sanskrit, Zend, Old Persian, with their descendants), in Armenian, in Balto-Slavonic and Albanian, in the form of a sibilant, while in Greek, the Italic dialects, Germanic and Celtic, it appears as a *k*-sound (see INDO-EUROPEAN LANGUAGES). Here the linguistic area is extremely wide, and it is clear that the difference between the two groups of languages must be dated back to a very early period. Again, it is a phonetic law of Greek that the original combination *st-* at the beginning of words is retained in Greek. How then are we to explain the existence side by side of *στέγος* and *τέγος*? The former apparently complies with the law, the latter does not. The former has by its side the verb *στέγω*, while *τέγος* is supported only by the rare *τέγη*. Yet the forms of the verb and substantive found in the Germanic languages leave no doubt that the forms without *s-* represent an extremely old form, for the English *thatch* could not have changed its original *t-* into *th-* if it had been preceded by *s-*, the law being as strict for English as for Greek that initial *st-* remains unchanged. On the other hand, a phonetic law may be limited to a very small area. Thus in the dialect of Eretria, and nowhere else within the area of the Ionic dialect of ancient Greek, do we find the change of the sound which appears elsewhere in Greek as *-σ-* between vowels into *-ρ-*: *σίτηριν* for *σίτησιν* (acc. sing.), *παραβαίνωριν* for *παραβαίνωσιν* (3rd pl. subjunctive). Why this change should take place here and nowhere else we do not know, although it may be conjectured that the cause was a mixture with immigrants speaking a different dialect, a mixture which ancient tradition supported. Undoubtedly such mixtures are the chief conditions of phonetic change, the effect of which is universal. The manner in which the change takes place is that the basis of articulation, the method in which the sound is produced, becomes changed. Thus along the "Highland line" in Scotland, where the English and Gaelic-speaking populations had their linguistic frontier for centuries, the *wh-* of English, the Anglo-Saxon *hw-*, becomes universally *f-*, *wha?* becoming *fa?* *white*, *fite*, &c., *f* being the sound which it was most easy to substitute for the difficult *hw-*. The history of Spanish in the different communities of South America excellently illustrates this point. After the discovery of America there was a large influx of Spaniards into Chile, who ultimately, and chiefly by intermarriage, incorporated amongst them a considerable element from amongst the native Araucanian Indians. The result has been

that the language of Chile is Spanish, pronounced not with the genuine sounds of Spanish, but with the sounds of the Araucanian language substituted for them. Elsewhere in Spanish America the language of the conquerors remained comparatively pure, because the Spaniards were much fewer in number, and had therefore to maintain themselves as a caste apart. For the same reason Latin has split up into the numerous branches which we know as the Romance languages. The particular line of development which, *e.g.* French followed as compared with Spanish or with the language of the Rhaetian Alps was conditioned by the nature of the sounds in the language which preceded it in the same area, and which was spoken by the ancient Gauls who adopted Latin. The difficulty found in all of these cases is precisely of the same kind as that which an adult at the present day speaking one language finds in attempting to learn the pronunciation of another language. On the one hand, it is only with the greatest difficulty that muscles for many years accustomed to perform one set of movements can be forced into performing another set which are very similar but yet not identical; on the other hand, to an untrained ear the difference between the two sounds may remain unappreciated. The result is that the new language is pronounced with the sounds of the speaker's original language. If the new language is adopted by a whole people to whom it was originally foreign, the children naturally learn it from their parents with the sounds of the old language which has now become obsolete. Thus the basis of articulation is changed, and if, as was the case with Latin, this process be frequently repeated among peoples speaking languages with articulation widely differing one from another, it is clear that a series of different dialects of the adopted language has been created. This kind of change is immediate and universal throughout the whole area where linguistic change has taken place.

Analogical change, on the other hand, does not affect the pronunciation of a language as a whole in the way that phonetic change does, but is confined to the formation, inflexion, syntax and meaning of single words or groups of words, and therefore is very apt to bear an entirely arbitrary and irregular character. A few instances will be sufficient to illustrate this and also to show how the apparently irregular phenomena of analogy may be classified. (*a*) In Old English a certain number of substantives formed their plurals by mutation of the root vowels, as *fōt, fēt,* or *bōc, bēc.* In Modern English this system of inflexion has been preserved in some cases, as in *foot, feet,* and altered in others, as *book, books.* Now, while *foot, feet* and *book* are the regular modern phonetic equivalents of the old *fōt, fēt, bōc,* the plural *books* can in no way be phonetically traced back to the old *bēc,* the phonetical equivalent of which in Modern English would be **beech.* The only possible explanation of a form like *books* is that the older *bēc* was at some date given up and replaced by an entirely new formation, shaped after the analogy of the numerous words with a plural in *-s* without modification of the root-vowel. Such changes, which are very numerous, exemplify the first kind of analogy, which is generally termed *formal* analogy. Other examples are the almost entire disappearance from the language of the forms in *er* and *en,* which were earlier used as plurals in English. That they were originally stem and not case suffixes does not affect the point. In Middle English, as in Modern English, *oxen* was spelt as a plural; *oxen* survives, but *eyen,* except in such dialect forms as the Scotch *e'en,* has been replaced by the form in *-s* : *eyes.* Similarly in Middle English the suffix *-er* existed in many words which had been originally of the neuter gender. Thus the plural of *child* was *childer,* of *calf* was *calver,* traces of which, besides the survival in dialect of *childer* and of *calver* (become by the 16th century in northern Scotch *cār*—pronounced as *cahr*—which is still in common use), are to be found in the place, and hence personal, names Childer-ley and Calver-ley. The old plural of *brother* was *brēther,* where the suffix, however, contained an original *-r,* not *-s* changed into *-r,* as did *childer* and *calver.* In Old English, alongside the form for *child* making a plural *childer,* there had been a masculine form making its plural in *-s.* It would not have been surprising therefore if in Modern English the plural of *child* had been *childs.* But in spite of the common tendency to make the plural of all noun-stems in *-s, child* has gone in the opposite direction and has not only maintained its *-r,* but has added to it the *-en* of stems like *oxen* and *eyen.* In Wiclif we find a similar plural to calf, *calveren*, but here *calves* has long replaced in the literary language both the earlier forms.

(*b*) Let us now take another instance from the English verb. In Old English the different persons of the preterite indicative in the so-called strong (irregular) verbs were generally distinguished by different root-vowels; *rīdan,* "to ride," and *bindan,* "to bind," for instance, form their preterites thus: *ic rād, ðū ride, hē rād, wē, gē, hīē ridon,* and *ic band, ðū bunde, hē band, wē, gē, hīē bundon.* In Modern English this difference in the root-vowels has been abandoned, and *rode, bound* now stand for all persons, *rode* being the modern phonetic equivalent of the 1st and 3rd sing. *rād,* while *bound* represents the *u-* form of *bindan.* When one form or set of forms ousts other varying forms from the same paradigm, the change is described variously as *material* or *logical* analogy. Inasmuch as a similar process of levelling to that seen in *rode* has been carried through in all preterites of Modern English, regularity prevails even here, though a few traces of the old conflict are still visible in such poetic forms as *sung* for the preterite side by side with *sang.* But when we look to its results in the individual verbs we soon find that the choice amongst the different forms which might have served as starting-points has been entirely arbitrary. It is indeed impossible to say why the old singular form should have been chosen as a model in one case, as in *rode,* and the old plural form in another, as in *bound.* From these and numerous similar instances we must draw the conclusion that it is beyond our power to ascertain whence analogical changes start, and to what extent they may be carried through when once begun. All we can do is to classify carefully the single cases that come under our observation, and in this way to investigate where such changes are especially apt to take place and what is their general direction. As to the latter points, it has been observed before that levelling of existing differences is one of the chief features in analogical change (as in the case of *rode* and *bound*). As to the former, it must be borne in mind that, before any analogical change can take place, some mental connexion must exist between the words or forms serving as models and those which are remodelled after the types suggested to the minds of the speakers through the former. Of such natural mental combinations two classes deserve special notice: the mutual relationship in which the different, say inflexional, forms of the same word stand to each other, and the more abstract analogies between the inflexional system of word-groups bearing a similar character, as, for instance, the different declensions of nouns and pronouns, or the different conjugations of verbs. The instance of *rode, bound* may serve to illustrate the former category, that of *books* the latter. In the first case a levelling has taken place between the different forms of the root-vowels once exhibited in the different preterite forms of *rīdan* or *bindan,* which clearly constitute a natural group or mental unity in consequence of their meaning. The form of *rode* as a plural has simply been taken from the old singular *rād,* the long *a* of which has become in *Modern* English *ō,* that of *bound* as a singular from the old plural *bundon,* the *u-* sound of which has in Modern English come to be pronounced as a diphthong. In the case of *book, books* for *bōc, bēc,* this explanation would fall short. Although we might say that the vowel of the singular here was carried into the plural, yet this would not explain the plural *-s.* So it becomes evident that the old declension of *bōc, bēc* was remodelled after the declension of words like *arm, arms,* which had always formed their plurals in *-s.* The changes indicated may generally be shown by a proportion, the new analogical formation being the unknown quantity to be ascertained. Thus in the case cited above, *arm* : arms = book : x; and clearly the form to be ascertained is *books.* Isolated words or forms which are no part of natural groups or systems, inflexional, formative or syntactical must be regarded as commonly safe from alterations

through analogy, and are therefore of especial value with regard to establishing rules of purely phonetic development.

(*c*) In syntactical analogy the mental connexion between the two series of constructions between which the change takes place is generally still more conspicuous. The connexion may be one of similar or of contrasted meaning. In Latin, adjectives of fullness, like other adjectives, no doubt originally were followed by the genitive case; participles, on the other hand, were followed by the instrumental ablative. Thus Plautus in the *Aulularia* 813 and elsewhere could say *aulam auri plenam*, "a pot full *of* gold," or 802 *aulam onustam auro*, "a pot laden *with* gold." From these the transition was easy to the construction *aulam onustam auri*, as if in English one should say (as was possible in Earlier English), "a pot laden *of* gold." In English, contrasted words often tend to assimilate their syntactical constructions. Thus, the adjectives *like* and *similar* are followed by the preposition *to* (though in Modern English *like* need have no preposition), and upon the analogy of such words, *different* and *averse*, with which correct speakers and writers couple *from*, are by no means rarely followed by *to*. Nor is it uncommon to hear or to see *differ with* instead of *differ from*, upon the analogy of *agree with*. Curiously enough, Latin, from which *differ* is descended, is found to follow the same analogy even in good writers. Thus Cicero (*Academica Pr.* ii. 143) combines *dissidere* with *cum*, as later does Seneca (*Epistulae*, 18. 1).

(*d*) In the development of analogy in meaning, similarity of sound is often the effective cause. Thus *impertinent* is properly *irrelevant*, *not to the point*, and is still so used in legal language; its more common signification of "saucy" arises from its accidental resemblance in sound to *pert*, a word which curiously enough has reversed its meaning, being now used in the sense of *mal-apert*, while the Old French *apert*, *aspert* (a confusion of Lat. *apertus*, "open," with *expertus*, "skilled"), meant both "open" and "skilful." Thus from very early times the verbs *fly* and *flee* have been confused, though they are of entirely different origins. When Middle English began to lose its verb endings in *-en*, it was very easy for the verb *leren*, "teach," and *lernen*, "learn," to be confused. Hence frequently in Elizabethan English *learn* stands side by side with *teache* in the same signification. Cf. Tottell's Miscellany, p. 129 (Arber):

> "I would not have it thought hereby
> The dolphin swimme I meane to *teache*:
> Nor yet to *learn* the Fawcon flie:
> I rowe not so farre past my reache."

It is true that the distinction between phonetic and analogical change has always been acknowledged in comparative philology. At the same time it cannot be denied that analogical changes were for a long time treated with a certain disdain and contempt, as deviations from the only course of development then allowed to be truly "organic" and natural, namely, that of gradual phonetic change (hence the epithet "false" so constantly attached to analogy in former times). Amongst those who have recently contributed most towards a more correct evaluation of analogy as a motive power in language, Professor Whitney must be mentioned in the first place. In Germany Professor Scherer (*Zur Geschichte der deutschen Sprache*, 1868) was the first to apply analogy as a principle of explanation on a larger scale, but in a wilful and unsystematic way. Hence he failed to produce an immediate and lasting impression, and the merit of having introduced into the practice of modern comparative philology a strictly systematic consideration of both phonetic and analogic changes as co-ordinate factors in the development of language rests with Professor Leskien of Leipzig, and a number of younger scholars who had more or less experienced his personal influence. Amongst these Brugmann, Osthoff and Paul rank foremost as the most vigorous and successful defenders of the new method, the correctness of which has since been practically acknowledged by most of the leading philologists of all shades of opinion.

The New School.

While the syntax of individual languages was one of the first features which attracted the grammarians' attention, at any rate in so far as particular authors differed from a given standard, it is only in very recent times that syntax has received methodical treatment from the comparative point of view. It may indeed be said that almost the whole fabric of the comparative syntax of the Indo-European languages as it exists to-day has been reared by one man—Professor Berthold Delbrück of Jena. In a series of brilliant studies beginning with a pamphlet on the Locative, Ablative, and Instrumental, published in 1867, and continued in his *Syntactical Researches* (*Syntaktische Forschungen*) in five volumes, comprising a treatment of the conjunctive and optative moods in Sanskrit and Greek (1871), the theory of the Sanskrit tenses (1877), the order of words in early Sanskrit prose (Çatapatha Brahmana; 1878), the foundations of Greek syntax (1879), and the syntax of the oldest Sanskrit (*Altindische Syntax*), dealing exclusively with the literature of the Vedas and Brahmanas (1888), Professor Delbrück laid the foundations for his treatment of comparative syntax in three volumes (1893, 1897, 1900), which has formed the completion of Brugmann's *Grundriss der vergleichenden Grammatik der indogermanischen Sprachen*. The only work by another hand (on a large department of the subject) which deserves to be mentioned by the side of Delbrück's studies is the small treatise by Hübschmann on the theory of the cases (*Zur Casuslehre*, 1875). For the comparative neglect of this field of investigation there are several reasons. The earlier philologists had so much to do in determining the languages which should be included within the Indo-European group, and in organizing the field of research as a whole, that it is not to be wondered at if they were unable to devote much attention to syntax. In the 'seventies, when attention began to be more directed towards comparative syntax, the remarkable discoveries made by Verner with regard to accentuation, and by Brugmann, Collitz and others with regard to the phonology of the Indo-European languages, again distracted attention from the subject. Moreover, the research in itself is infinitely more difficult than that into sounds and forms; for the latter may be carried on by the help of grammars and dictionaries with a comparatively small knowledge of the literature of any individual language, while on the other hand the study of syntax is impossible without a thorough and intimate knowledge of the literature and modes of expression in each separate language. It is not, therefore, matter for wonder that Delbrück has confined himself in the investigation of syntax to a part only of the languages whose sounds and forms are discussed by Brugmann in the earlier volumes of the *Grundriss*. To cover the whole ground is beyond the powers of a single man, and there is a great lack of preliminary studies on the syntax of many of the languages.

Historical Syntax.

One of the most difficult problems connected with syntax, but primarily, as it appears, a question of morphology, is the origin of grammatical gender. It cannot be said to be an advantage to the languages which possess it, while languages which, like English, have dropped it except for an occasional metaphor, suffer no loss. Nor is the problem confined to the history of gender in the substantive. Even more perplexing is the introduction of gender into the adjective. The pronouns of the first and second persons, which are certainly very old, show no trace of gender; the pronouns of the third person, which are more of the nature of deictic adjectives, generally possess it. To the question how grammatical gender arose in the substantive, the answer was till comparatively recently supposed to be that primitive man was given greatly to personification, endowing inanimate things with life and attributing to them influences benign or the reverse upon his own existence. The answer is not quite sufficient, for though this tendency to personification, which philologists have perhaps unduly decried or altogether denied, might account for life being attributed to inanimate objects, it hardly explains why some should be treated as masculine and others as feminine. Nor is it true, as has also been suggested, that in the case of the lower animals the generic name for the larger and stronger animals is masculine and that for the smaller or weaker feminine. In both Greek and Latin the wo..

is masculine and the fox feminine, but the lamb or the chicken which the fox robs from the fold or the henroost is rarely feminine, generally masculine. Nor does this explanation account for the mouse in those languages being of the masculine gender, while the ferret or cat which caught them is feminine (γαλῆ, *feles*). An explanation which completes the theory of personification, if it does not altogether drive it from the field, has been put forward by Brugmann.[1] In its briefest form this explanation is that gender was attached to certain suffixes because they chanced to occur frequently in words which markedly implied sex. In the Indo-European languages the commonest suffix indicating feminine gender is *ā*. According to this theory it had originally nothing to do with gender, but as some early words for woman or wife ended with this sound it came to be identified with feminine gender. Similarly the ending *os* in *o*-stems occurred often in names connected with males and so became identified with the masculine gender. But many stems indicate either gender indifferently, and even the very old sex words *father* and *mother* have the same ending. But when masculine and feminine endings have been attached to certain suffixes in this way, how comes it that in one series of stems the neuter should be marked not by an absence of all suffix but by a separate suffix in *-m*? These are the *o*-stems, other forms of which have been markedly identified with the masculine gender. As this characteristic, like the others mentioned, goes back apparently to a time before the separation of the Indo-European languages, explanation can hardly pass beyond speculation. It is, however, to be noted that the neuter form of the nominative is phonetically identical with the accusative form of the masculine, and it has been ingeniously argued[2] that such forms were used originally in the accusative, such neuters not forming the subject to a verb. To the same writer the most plausible explanation of the presence of gender in the adjective is due, viz. that gender began with the deictic pronoun **so* "that man," **sā* "that woman," and that hence it passed to the adjective with which the pronoun was so frequently accompanied. If this explanation be right, analogy has brought into the Indo-European languages the useless multiplication of gender marks in such sentences as the Latin *hae pulcrae feminae caesae sunt*, where the feminine gender is indicated no less than four times without any obvious gain over the English *These fair women were slain*, where grammatical gender is no longer obviously indicated at all.

Closely related to this question is that of the history of the neuter plural, which was first fully worked out by Professor Johannes Schmidt of Berlin.[3] The curious construction, most common in ancient Greek, whereby a neuter plural is combined with a singular verb, is now demonstrated to be an archaic survival from the time when the neuter plural was a collective singular. Thus a word like the Latin *iugum* was a single yoke, the plural *iuga*, however, which was earlier *iugā*, was a collection of yokes, with the same final *ā* as is found generally in feminine substantives. The declension ought therefore to have been originally: nominative *iugā*, genitive *iugās*, &c., like *mensa*, &c., of the first declension. But as *iuguum* was used in the neuter singular for both nominative and accusative, *iugā* when it was felt as the corresponding plural was used for the accusative as well as the nominative, while the other cases of the plural were taken over from the masculine *o*-stems, with which the singular neuter in *-o-m* was so closely connected. That collective words should be used for the plural is not surprising; the English *youth*, first an abstract, next a collective, and finally an individual, is a case in point.

For the early history of the syntax of the verb Greek and Sanskrit are important above all other languages, because in them the original forms and the original usages are better preserved than they are elsewhere. And it is in the verb that the great difficulties of comparative syntax present themselves. The noun system is so well preserved in several languages that, when the number of the original cases had once been determined, the sifting of the pro-ethnic usages attaching to each case was tolerably easy, for besides Sanskrit and (to a less extent) Latin, Lithuanian and Slavonic have kept the pro-ethnic case system almost complete. The ideas also which had to be expressed by the cases were on the whole of a very concrete character, so that here the problem was much simplified. On the other hand, the ideas expressed by the forms of the verb are of a much more subtle nature, while the verb system in all languages except Greek and Sanskrit has broken down earlier and more completely than the noun. It is clear that the verb of the original Indo-European language possessed two voices, and forms corresponding to what we call the Indicative, Subjunctive, and Optative moods, and to the Present, Imperfect, Future, Aorist, and Perfect tenses. The imperative mood seems primitively to have been confined to the second person singular, just as the vocative, which, like the imperative, is a stem form without suffix, was confined to the singular. The infinitive, as is well known, is in all languages of this system not originally a verbal but a substantival form. The pluperfect, where it has developed, seems to be a mixed form arising from the application of aorist endings to a perfect stem. Thus far the history of the verb system is tolerably clear. But when we attempt to define the original meaning of the moods and of the tenses we pass into a region where, in spite of assiduous investigation in many quarters during recent years, the scanty amount of light thrown on the problem has only served to make the darkness visible. As regards the tenses, at least, it has been shown that without doubt there is no difference in formation between present, future and aorist stems, while the earliest meaning of the perfect was that of a special kind of present expressing either repeated or intensive action or a state. It has also been proved that the original meaning of the aorist is not past in time, and that in fact the only element whereby these languages could express remoteness in time was the augment. The augment seems to have been originally a pronominal deictic particle. Thus, as there was no original pluperfect, as neither perfect nor aorist originally referred to past time, and as the future, except in Lithuanian (with slight traces in Slavonic) and the Indo-Iranian group, cannot be clearly distinguished from the aorist, the system as a method of expressing time absolutely breaks down. The tenses in fact did not originally express the times when the action took place, but the type of action which took place. Thus the present system in the main expressed continued or durative action, the aorist only the fact that the action had taken place. The action indicated by the aorist might have been of considerable duration, or it might have been begun and ended in a moment; its characteristics in this respect are not in any way indicated by the aorist form, which intimates only that the action is viewed as a completed whole and not as a continuous process. The present system, however, is built up in a great variety of ways (thirty-two according to Brugmann's enumeration). It is a priori unlikely that such a multiplicity of formations had not originally some reason for its existence, and Delbrück thinks that he has discovered a difference in syntactical value between various forms. The reduplicated present forms of the type seen in Sanskrit *jigāti*, Greek δίδωμι, &c., he regards as expressing originally an action which consisted of repeated acts of the same nature (iterative), though this iterative meaning frequently passed into an intensive meaning. Presents of the type seen in Sanskrit *tṛ́ṣyati*, "is thirsty," and Greek χαίρω, "am glad" (for *χαρι̯ω), where the *i̯* (*y*) of the suffix has modified the first syllable and disappeared, he regards as *cursive*—*i.e.* they express continuous action without reference to its beginning or end. Verbs which have regard to the beginning or end of the action he calls terminative, and finds them represented (*a*) in verbs with *-n-* suffixes, Sanskrit *ṛṇóti*, ὄρνυσι, "sets in motion," ἄγνυμι, "break to pieces"; (*b*) in verbs with the suffix *-sko-*, Sanskrit *gáchati*, "goes" (to a definite destination), Greek βάσκω, &c. The roots he classifies as momentary (punktuell) or non-momentary, according as they do or do not express an action which is begun and ended at once.

[3] *Pluralbildungen der indogermanischen Neutra* (1889).

This method of classification was no doubt suggested in the first instance by the characteristics of the Slavonic verb system. In this system a clear distinction is drawn in nearly all verbs between those which express a process (durative verbs) and those which express a completed action (perfective verbs). When perfective and durative verbs are formed from the same root, the perfective are distinguished from the durative forms (*a*) by having a preposition prefixed, or (*b*) by having a different stem formation. Thus in the Old Bulgarian (Old Ecclesiastical Slavonic) *to strike* (hit) and *to strike dead* are expressed by the same verb, but in the latter meaning a preposition is found which does not appear in the former, *biti* (infinitive), "to strike"; *u-biti*, "to strike dead." *To strike* is *durative*; *to strike dead* is *perfective*. As an example of difference of stem formation expressing this difference of meaning, we may quote *sěsti*, "to sit down" (perfective), *sěděti*, "to sit" (durative). Verbs with a suffix in *-n-* have often a perfective meaning: cf. the Sanskrit and Greek verbs quoted above. The *perfective* verbs correspond in meaning to the Greek aorist, and are to be carefully distinguished from *perfect* forms. The same distinction of meaning is often achieved in other languages also by means of prepositions, *e.g.* in Latin (Seneca, *Epp.* xciii. 10), *Quid autem ad rem pertinet, quamdiu* vites, *quod* evitare *non possis?* "What does it matter how long you go on avoiding [durative] what you cannot escape [perfective]." From this example, however, it is clear that, though the means employed to make the distinction are different, there is no difference in meaning between such perfective verbs and those classified by Delbrück as terminative. Here, as in many other parts of this study, the ideas are new, and grammatical terminology has not yet sufficiently crystallized, and still leaves something to be desired both in clearness and in precision.

As regards the moods, the difficulty has been to find any criterion whereby the functions of one mood should be differentiated from those of the others. It has long been recognized that the difference between indicative and subjunctive is one of meaning and not one of formation; that, *e.g.*, in Sanskrit *bharati* (3rd sing. pres. indic.), "bears," is morphologically identical with *hanati*, "may slay" (3rd sing. pres. subj.), and that the latter is described as a subjunctive only because of the meaning, and because there exists a dissyllabic form, *hanti*, which makes the indicative "slays." Similarly in Greek it is impossible to distinguish morphologically between παύσω, "I shall check" (fut. indic.) and παύσω, "let me check" (1st aor. subj.). Moreover, in the earliest forms of the languages which preserve the moods best (Greek and Sanskrit), the connexion syntactically between the indicative and the subjunctive forms is closest. Not only does the future express futurity, but also the determination of the subject to carry out the action expressed, which, in Delbrück's discussion of the moods, is precisely the point chosen as characteristic of the subjunctive. On the other hand, the present optative differs from the present (and future) indicative and present subjunctive in having a special mood suffix, and in having secondary while they have primary personal endings. Nevertheless its meaning overlaps that of the other forms, and some excellent authorities, like Professor W. W. Goodwin, see in future indicative, subjunctive and optative only different degrees of remoteness in the future, the remoteness being least in the future and greatest in the optative. Delbrück, however, abides, with slight modifications, by the distinction which he propounded in 1871 that the subjunctive expresses Will and the optative Wish. Here again the problem has not been solved, and it is doubtful how far any definite solution is likely to be arrived at, since there are so many gaps in our knowledge of mood forms. These gaps, owing to the break-up of the system at so early a period, it is hardly probable we shall ever be able to fill. It is possible, however, to do a great deal more than has yet been done even in the most familiar languages. In Latin, for instance, even now, the facts for the uses of the moods within the two centuries of the classical period are very imperfectly known, and it is no exaggeration to say that more has been done in the last hundred years for Sanskrit than has been done in two thousand years of continuous study for Latin or Greek.

A still later addition to the domain of Philology—the study of meaning—presents fewer difficulties, but until recent years has been equally neglected. The study is so recent that the literature of the subject is still extremely small. The only attempts to deal with it on a large scale are M. Bréal's *Essai de Sémantique* (1897), now translated into English under the title of *Semantics* (1900), with a valuable introduction and appendix by Dr Postgate, and M. de la Grasserie's *Essai d'une Sémantique intégrale* (1908), a work which deserves mention for its attempt to make a thorough classification and a corresponding terminology for semantic phenomena, but the value of which is much diminished by hasty compilation and imperfect knowledge of many of the languages quoted. From the practical point of view many of the phenomena have been classified in works on rhetoric under the headings of Metaphor, Synecdoche and Metonymy. The psychological principle behind this superficial classification is that of association of ideas. Here, as elsewhere, changes proceed not by accident, but according to definite principles. Here, as elsewhere in language, in history, and the other moral sciences, the particular principle in operation can be ascertained only by beginning with the result and working back to the cause. In the development of meaning much more than in phonetics is this necessarily the case. In phonetics all speakers of the same dialect start with approximately the same sound. But the same combination of sounds which we call a word does not recall the same idea to all persons who use that word. The idea that the phrase *railway station* calls up in the mind of a Londoner is very different from that which occurs to the mind of a child acquainted only with a wayside station serving the wants of a country village of a few hundred inhabitants. The word *herring* suggests one idea or train of ideas to the fisherman who catches the fish, another to the merchant who purchases it from the fisherman, a third to the domestic who cooks it, and so on. To members of the same family the same word may often have widely different associations, and, if so, the metaphors for which the word will be employed will differ in each case.

For the history of meaning it is necessary to have regard to all the forms of association of ideas which psychology recognizes. These are contiguity in place or in time, resemblance and contrast. Contrast, however, as J. S. Mill and Bain have shown, is not a simple form of association, but is evolved partly from contiguity, partly from resemblance. An artificial hollow generally implies also an artificial height made of the materials excavated from the hollow. Hence in most languages some words occur with the two contrasted meanings. Thus in English we find *dyke* in use both for a ditch and for a mound fronted by a ditch, the word *ditch* being, in fact, but a dialectal form of *dyke*. In Scotland, on the other hand, where earthen mounds and stone walls form more frequent boundaries between fields than in England, the word *dyke* is now practically limited to elevated boundaries, while *ditch* is limited to excavated boundaries. Thus the proverb, "February fill dyke," which in England implies that the February rains will fill the ditches, is often understood in Scotland to mean that in February the snow will be level with the tops of the stone or turf walls. Similarly in Latin Tacitus can say *fossas proruere*, which can only apply to levelling raised mounds; while in Greek Xenophon also talks of the ditch (trench) thrown up (τάφρος ἀναβεβλημένη). It is only natural, therefore, that other words with several meanings should be used similarly: *moat*, originally a mound of earth or peat, has come to mean a big ditch; while, conversely, soldiers in trenches are not so much in ditches, as the word ought to signify, as behind breastworks. Sometimes, when two actions opposed to one another are contiguous, a word seems to change to the exact opposite of its original meaning. Thus the English verb *wean*, which meant originally to accustom (to cooked food), has been transferred to the necessary preliminary, to disaccustom to the breast.

Resemblances may be (i.) genuine, and (*a*) of external appearance, or (*b*) of other characteristics; or (ii.) fanciful or analogical. From resemblance in the external appearance of the object, the word *gem*, which in Latin (*gemma*) usually means a bud, has

come to mean first a pearl and then by extension of the meaning any precious stone. From the concentric coats which appear in both, the Latin word for a pearl (*unio*, acc. *unionem*) appears in English as *onion*. Examples where the characteristics are not of external appearance are such as the German *kaiser* and the Russian *tsar*, which are descended from Julius Caesar, while the Lithuanian word for king—*karālius*—is *Carolus*, *i.e.* Charlemagne. So in modern Persian, *Xusrev*, "Lord," comes from the Zend proper name Husravah (Chosroes). As already pointed out, the resemblances which have established a connexion between *pert* and *impertinent* (properly irrelevant) are in sound only. The same is true of the supposed relation of the verb *cut* to *cutlass*, *cutler* and *cutlet*. While *train oil* really means oil in drops like tears (cf. German *Thräne*), most people connect it with railway trains. The resemblance in some cases is merely in function. Thus, though the fir and the oak have no resemblance one to the other, the word *fir* is now generally identified with the Latin *quercus* in etymology (cf. *four* and *quattuor*), in the same way as the Latin *fagus*, "beech," is with the Greek φηγός, "oak," the users of the word having, in the course of their migrations, passed from a land with oaks to a land with firs in the one case, and from a land of beeches to a land of oaks in the other. Resemblance as the basis of metaphor has a very widely extended influence on language.

The most numerous and most varied forms of change in meaning depend, however, upon the law of contiguity. Perhaps the commonest of all forms of contiguity is that where the word indicating some accompanying feature or condition replaces the word for the object referred to. In the countries that border the Mediterranean the heat of midday is accompanied and intensified by the dying away of the wind, a characteristic remarked upon by Aeschylus (*Agam.* 565): "What time upon his noonday couch, windless and waveless sank the sea to rest." From the Greek word καῦμα, "burning heat," arises through Late Latin the English *calm*, where the absence of wind is the only idea present, that of heat having altogether disappeared. Again, in *bugle*, which is abbreviated for *buglehorn*, the word which survives properly means *wild ox*, and the originally more important element is lost. In a combination like *silver bugle* the word has gone a stage further; the original meaning of horn has also disappeared. There is no longer any thought of an animal's horn; the only idea that survives is that of a musical instrument. From the cope or cloak (*capella*) of St Martin, which was preserved as a sacred relic by the Frankish kings, comes the word *chapel*. The word was first transferred from the cloak to the holy place wherein it was kept, and thence to similar shrines, and ultimately to any place, not being a church, where prayers were said. A *jig* was originally not the dance, but the fiddle which supplied the music for the dance. The names of liquors are often replaced by some accompaniment as of the place, *port*, *sherry*, *champagne*, or by a qualifying adjective as in *brandy*, properly "burnt," from the Dutch *brandewijn*; or, again, only the less important element of the word is retained as in *whisky*, literally "water," for the older *usquebaugh*, a corruption of Gaelic words meaning the "water of life" (*aqua vitae*). Replacement of substantives by their accompanying adjectives is common in most languages. One of the most common methods of coining a name for a new article is to give it the name of the place or people whence it comes. Thus we have arras, lawn (from Laon), cravat (Croat), coach from Kocs in Hungary, bilboes (both fetters and swords) from the iron mines of Bilboa in Spain. Equally common are the names of inventors—pinchbeck, tontine, silhouette, guillotine, derrick. In the word *cash*, which comes indirectly from Latin *capsa*, "a box," the thing contained has taken its name from the container. Similarly *mortar*, "cement," derives its name from the mortar in which it was mixed, while in *box* the material (boxwood, Lat. *buxus*, Greek, πύξος) has usurped the place of the article made. In *leper* the disease (Lat. *lepra*, the rough disease, from Greek, λεπρὰ νόσος) has been made into the name of the sufferer, who was earlier called a leprous man. As a consequence, a new substantive *leprosy* has to be taken from the adjective to indicate the disease. The various changes in meaning, which are classed together as synedoche, have their origin in contiguity. Thus we have the species for the genus; the butcher, who properly kills goats only (Old French *boc*), has ousted the flesher. But we have also the genus for the species; corn, as a rule, means in England wheat; in Scotland oats; in America, maize. The individual becomes collective as in corps, navy, body (of men); the collective becomes individual when Latin *racemus*, "bunch of grapes," passes into English "raisin." Here would come the so-called meliorative and pejorative developments in word-meaning, whereby, *e.g.* *steward*, "the sty-ward," becomes the title of a great officer of the realm and the name of a line of kings; or, on the other side, *sou* (Latin *solidus*) passes from the name of a gold coin to that of one of proverbially insignificant value. Here, too, would come many euphemistic uses which are, for the most part, applications of more general terms to avoid the mention of some specific act or object which is unpleasant, as death, murder, bankruptcy, debt, &c., while metaphorical terms for the same things come under resemblance. These examples do not exhaust the forms of contiguity which appear in language, but they are enough to show how far-reaching the effect of this type of association of ideas is upon language, and how extensive the field is which still calls for investigation before the study of meaning attains the same development as the investigation of the other branches of the history of language.

Authorities (since 1885).—For methods of Linguistic Study: Paul, *Principien der Sprachgeschichte* (3rd ed., 1898); Von der Gabelentz, *Die Sprachwissenschaft* (2nd ed., 1901); Strong, Logeman & Wheeler, *The History of Language* (1891), an adaptation of the ideas o Paul's *Principien*, with many excellent examples; van Ginneken, *Principes de Linguistique psychologique* (1907). For the Controversy regarding Phonetic Laws: Curtius, *Zur Kritik der neuesten Sprachforschung*; Brugmann, *Zum heutigen Stand der Sprachwissenschaft*; Schuchardt, *Über die Lautgesetze: gegen die Junggrammatiker* (all in 1885); Tarbell, "Phonetic Law," in *Transactions of American Philological Association* for 1886, pp. 1 sqq.; Wechssler, "Giebt es Lautgesetze?" (1900), Sonderabzug aus *Forschungen zur romanischen Philologie*: Festgabe für Hermann Suchier; Wundt, *Die Völkerpsychologie* (1900), vol. i.; Oertel, *Lectures on the Study of Language* (1901), lecture iv. For Analogy: Wheeler, "Analogy and the Scope of its Application in Language" (1887), *Cornell University Studies in Classical Philology*. For the Classification of Languages: Misteli, *Characteristik der hauptsächlichsten Typen des Sprachbaues* (1893). For the Phonology, Morphology and Syntax of the Indo-European Languages: Brugmann and Delbrück, *Grundriss der vergleichenden Grammatik der indogermanischen Sprachen* (1886–1900); a new edition of the *Phonology* by Brugmann in 1897, of the stem-formations and inflexion of Nouns, Adjectives, Pronouns and Numerals in two parts (1906, 1909); the first edition of the *Phonology and Morphology*, translated into English in four volumes by Wright, Conway and Rouse. For Discussion of Contested Points: Bechtel, *Die Hauptprobleme der indo-germanischen Lautlehre* (1892). For Syntax: Delbrück, in the works mentioned, in the text. For Semantics: besides Bréal and Postgate, see Wundt, *Die Völkerpsychologie*, vol. i. pt. 2, and articles by John Grote in the *Journal of Philology*, vols. iv. and v. A bibliography of the works which have appeared since 1890 will be found in the *Anzeiger für indogermanische Sprach- und Altertumskunde: Beiblatt zu den indogermanischen Forschungen redigiert*, by W. Streitberg.

(P. Gi.; E. Si.)

Summary of Philological Articles

In addition to the genetic classification of languages given above (on pp. 426–429), some further guidance as to the actual headings under which the philological section is arranged may be of service to the student.

The pivot of the whole section is the article Alphabet, which traces the history of language and writing to the earliest stages, embodying the results of archaeological studies in all countries, together with the general conclusions based thereon. In this article (with further details under Crete) will be found an account of the controversy regarding the Cretan discoveries of Dr A. J. Evans. Supplementary to this comparative survey are the articles Palaeography, Inscriptions, Writing and Phonetics. The first two deal with ancient documents of all kinds: Palaeography with those specimens of ancient writing, literary, economic or legal, which were committed to codices, tablets or rolls by the use of the stilus, the reed or the pen; Inscriptions with documents engraved on stone or metal.

WRITING deals, chiefly from the anthropological standpoint, with primitive attempts to record ideas in an intelligible form, *e.g.* with "knot-signs," "message-sticks," picture-writing and the like. PHONETICS covers the whole subject of speech sounds and pronunciation, the organs of speech and national sound systems.

Supplementary, from another point of view, to the article ALPHABET is a complete series of articles on the letters of the English alphabet. In these articles the history of the individual letters is traced from the Phoenician through Aramaic, Greek and Roman to modern times. All these articles may be read in connexion with a comparative table in the article ALPHABET (*ad fin.*), which shows in parallel columns the earliest equivalents of the modern English letters, *i.e.* Brahmi, Kharosthi, oldest Æthiopic, Sabæan, Nashki, Tema, Sindjirli, the Moabite stone, Phoenician, Greek, Latin, Cyrillic and Glagolitic. Another important comparative table of written signs is contained in the article SLAVS, showing the various Cyrillic, Glagolitic and Latin letters used by the Slav peoples.

Passing from articles dealing with the method and general subject-matter of philology, the student will find articles on the great families of languages, each with its subordinate articles on special languages and dialects.

1. *Indo-European Languages.*—Of articles on language-families, the most important is that under the heading INDO-EUROPEAN LANGUAGES. This great division, which is dealt with from the comparative standpoint in the second part of the article PHILOLOGY, is under its own heading treated in detail. The article begins with a sub-classification into two main groups—the so-called (A) *centum* and (B) *satem* groups—each of which is further divided into four sections. In accordance with this classification there are separate articles on the individual ancient and modern languages and dialects.

A. (1) GREEK LANGUAGE (supplemented by sections under HOMER, DORIANS, &c.); (2) LATIN LANGUAGE (with OSCA LINGUA, IGUVIUM, &c., and articles on the Italic tribes and places, *e.g.* VENETI, CAERE); (3) Celtic, *s.v.* CELT (with subsidiary articles); and (4) Teutonic, *s.v.* TEUTONIC LANGUAGES, SCANDINAVIAN LANGUAGES, and the like.

The modern descendants of these languages are all further treated separately. Thus following LATIN LANGUAGE is the article ROMANCE LANGUAGES, which traces the development of the Latin tongue during its gradual differentiation into Italian, French, Spanish, Rumanian, &c.; while a more detailed account of these will be found under ITALIAN LANGUAGE; FRENCH LANGUAGE; SPAIN: *Language*; RUMANIA: *Language*. There is also a special article PROVENÇAL LANGUAGE, dealing with the Romanic speech of southern France. The Teutonic languages are similarly dealt with in detail under ENGLISH LANGUAGE (including Anglo-Saxon); DUTCH LANGUAGE; GERMAN LANGUAGE. SCANDINAVIAN LANGUAGE itself includes Icelandic, Norwegian, Swedish, Danish.

B. In the *satem* group of the Indo-European family the four divisions are as follows:—

(1) Indo-Iranian or Aryan. This division may be subdivided into (*a*) Indo-Iranian, treated mainly in the article PERSIA: *Language and Literature* (including Zend, Old, Middle and New Persian, and the modern dialects), and (*b*) Indian. The Indian languages are discussed primarily under INDO-ARYAN LANGUAGES, which describes the relations of *Pisaca*, *Sanskrit*, *Prakrit*, and gives a paradigm of the various languages of the three great divisions of India. This central article refers to the separate articles PISACA, SANSKRIT and PRAKRIT, which in turn are supplemented by a number of articles on particular languages. Of these reference may be made to BENGALI; BIHARI; GUJARATI AND RAJASTHANI; HINDOSTANI; KASHMIRI; MARATHI; PALI. The gipsy languages, which may probably be assigned to the Indo-Iranian division, are described under GIPSIES.

(2) The account of Armenian will be found under ARMENIAN LANGUAGE AND LITERATURE.

(3) The Balto-Slavonic Languages. Of these the three comprised in the Baltic group, viz. Lithuanian, Lettic and Old Prussian, are described under the heading LITHUANIANS AND LETTS. For the Slavonic group, the chief article is SLAVS: *Language*, which deals with the elements common to all the Slavonic tongues, with their early history and differentiation. It contains a comparative table of alphabets. It is supplemented by an article OLD SLAVONIC, and by further information under the headings RUSSIA, BULGARIA, SERVIA, POLAND, BOHEMIA, CROATIA-SLAVONIA, SLOVAKS, SLOVENES, SORBS, KASHUBES, POLABS.

(4) The Albanian dialects are treated under ALBANIA.

2. *Semitic Languages.*—At the heading of this section stands the article SEMITIC LANGUAGES, supplemented by HEBREW LANGUAGE, ARAMAIC LANGUAGES, and linguistic sections under PHOENICIA, ETHIOPIA, and the like.

3. *Hamitic Languages.*—The central article in this family is HAMITIC LANGUAGES, which is supplemented, so far as the Cushitic or Ethiopian group is concerned, by further information in the articles EGYPT; ETHIOPIA; ABYSSINIA; SOMALILAND; and, so far as the Libyan group is concerned, by the articles BERBERS and KABYLES.

4. The chief feature of the *Monosyllabic* family is the section *Language* under CHINA, supplemented again by similar sections in articles on other countries of south-eastern Asia, and by the article TIBETO-BURMAN LANGUAGES. There is also a language section under Japan which discusses the affinities between Chinese, Korean and Japanese.

5. The *Ural-Altaic* family is described in outline in the article URAL-ALTAIC, which gives the general relationships of Turkish, Finno-Ugrian, Mongol and Manchu, and of minor subdivisions such as Syryenian, Mordvinian and Votyak. Turkish is discussed in the article TURKS: *Language*, which deals with Osmanli proper and the Tatar-Turkish languages generally. The article FINNO-UGRIAN is a comparative survey dealing with the language of the Finns, Lapps, Samoyedes, &c.; while Magyar is treated separately in HUNGARY: *Language*. Under MONGOLS there is a special section *Language*, discussing the three groups of East Mongol, West Mongol (including Kalmuck) and Buriat.

6. The principal languages of southern India, *e.g.* Tamil, Malayālam, Kanarese, Telugu, &c., are dealt with generally under the heading DRAVIDIAN; while there is a separate article TAMILS, containing a section on their language; and brief notes under the headings BRAHUI, TELUGU, MALAYĀLAM, &c.

7 and 8. The scattered languages of the Malay-Polynesian family and other Oceanic peoples are treated principally in the article MALAYS, which further information is given under the headings POLYNESIA; SAMOA; JAVA; NEGRITOS, BATTAS, &c.

9. The Caucasian family is described chiefly in the article GEORGIA: *Ethnology*. Further information will be found in CAUCASIA: *Ethnology*.

10. Of the remaining European languages only two need special mention: Basque, which is treated in a special section under the heading BASQUES; and the lost Etruscan, which is treated under ETRURIA and LATIN LANGUAGE.

11. The principal languages of southern and central Africa are treated fully under BANTU LANGUAGES. There is a brief account of the Bushman language under BUSHMEN, and of the Hottentot languages under HOTTENTOTS.

12. *Intermediate African Languages.*—Among the numerous languages spoken by the people of the great central belt of the African continent, the most important is the Hausa, described under that heading.

13. *America.*—The whole question of the languages of the North American Indians is dealt with in the article INDIANS, NORTH AMERICAN, which contains an elaborate linguistic paradigm.

Bibliographical information will be found in practically all the above headings. In addition to the most modern authorities there quoted, there will be found in the article DICTIONARY a very full list of older lexicographical works.

The above summary does not purport to present dogmatically a rigid philological classification. It disregards many problems, and is intended solely to enable the student readily to find the material of which he may be in search.

PHILOMEL (Fr. *philomèle*; Ger. *Philomele* or *Stahlgeige*), a musical instrument similar to the violin, but having four steel wire strings. The philomel has a body with incurvations similar to those of the guitar; therefore, without corner blocks, the outline of the upper lobe forms a wavy shoulder reminiscent of the viols but more ornate and fanciful. The peg-box sometimes terminates in a fancy head instead of a scroll. The philomel, never used in the orchestra, is the instrument of the dilettanti, frequently played in Germany with the bowed zither. The accordance of the philomel is the same as for the violin; the timbre is shrill and crystal-like. There is also an alto philomel corresponding to the viola. The bowed melodion is similar to the philomel, and has four steel strings of the same accordance as the violin, but arranged in inverse order; instead of being held like the violin and philomel, under the chin, it is placed on the knees of the performer, so that a hook under the finger-board rests against the table. (K. S.)

PHILON, Athenian architect of the 4th century B.C., is known as the planner of two important works—the portico of the great Hall of the Mysteries at Eleusis and an arsenal at Athens. Of the last we have exact knowledge from an inscription. E. A. Gardner (*Ancient Athens*, p. 557) observes that it "is perhaps known to us more in detail than any other lost monument of antiquity." It was to hold the rigging of the galleys; and was so contrived that all its contents were visible from a central hall, and so liable to the inspection of the Athenian democracy. (See ATHENS.)

PHILOPATRIS, the title of a dialogue formerly attributed to Lucian, but now generally admitted to be spurious. Its date and purport have long formed the subject of discussion. The scene is laid at Constantinople. A certain Triephon, who has been converted to Christianity by a bald, long-nosed Galilaean, who was carried up through the air into the third heaven (an evident allusion to St Paul), meets a friend, Critias, who is in a state of great excitement. Triephon inquires the reason, and the invocation of Zeus by Critias leads to a discussion on paganism and Christianity, in which all the gods proposed by Critias are rejected by Triephon, who finally suggests that Critias should swear by the Trinity. (The sub-title, ἢ διδασκόμενος, refers to this "instruction" of Critias in matters relating to Christianity.) Critias goes on to relate how he had been introduced to a gathering of pessimists, who predicted all kinds of disturbances in the empire and defeat at the hands of its enemies. In the meantime a third person appears on the scene, with the news that the imperial armies have obtained a glorious victory. The hope is expressed that Babel (Bagdad, the chief city of the caliphs) may soon be destroyed, Egypt subdued (that is, reconquered from the Arabs), and the attacks of the Scythians (Russians or Bulgarians) repulsed. The whole concludes with thanks to the unknown god of Athens that they have been permitted to be the subjects of such an emperor and the inhabitants of such an empire. The *Philopatris* was for a long time regarded as an attack upon Christianity, and assigned to the time of Julian the Apostate (emperor 361–363). Chronological indications (*e.g.* the allusion to a massacre of women in Crete) led Niebuhr to ascribe it to the reign of Nicephorus Phocas (963–969), and this view is now generally supported. There being at that time no pagans in Constantinople, the "pessimists" referred to must be Christians—either monks, especially the intimate friends of the patriarch of Constantinople, who, aggrieved at the measures taken by Phocas in regard to the property of the Church, were ready to welcome the defeat of the imperial arms and the ruin of the empire; or harmless visionaries, who claimed to predict the future by fasting, prayer and vigil. In any case, the author, whether he was a sophist commissioned by Phocas to attack the monks, or some professor who hoped to profit by singing the imperial praises, represents the views of the "patriotic" (as the title shows) as opposed to the "unpatriotic" party. According to another view, which assigns the dialogue to the time of Heraclius (610–641), the author was a Christian fanatic, whose object was to make known the existence of a conventicle of belated pagans, the enemies alike of the Christian faith and the empire; it is doubtful, however, whether such a pagan community, sufficiently numerous to be of importance, actually existed at that date. The object of the first and longer portion of the dialogue was to combat the humanism of the period, which threatened a revival of polytheism as a rival of Christianity.

BIBLIOGRAPHY.—Editions by J. M. Gesner (1715) and C. B. Hase in the Bonn *Corpus scriptorum hist. byz.* (1828), vol. xi.; also included in Jacobitz's edition of Lucian (1839). See R. Crampe, *Philopatris. Ein heidnisches Konventikel des siebenten Jahrhunderts zu Constantinopel* (1894); R. Garnett, "Alms for Oblivion" in *Cornhill Magazine* (May 1901); C. Stach, *De Philopatride* (Cracow, 1894), who shows its late origin by linguistic tests; S. Reinach in *Revue archéologique* (1902), vol. i.; B. G. Niebuhr, "Ueber das Alter des Dialogs Philopatris" in his *Kleine historische Schriften* (1843), vol. ii.; and, for further authorities, article by Von Dobschütz in Herzog-Hauck's *Realencyklopädie für protestantische Theologie* (1904).

PHILOPOEMEN (253–184 B.C.), Greek general, was born at Megalopolis, and educated by the academic philosophers Ecdemus and Demophanes or Megalophanes, who had distinguished themselves as champions of freedom. Avoiding the fashionable and luxurious gymnasia, he devoted himself to military studies, hunting and border forays. In 233–2 Philopoemen skilfully evacuated Megalopolis before the attack of Cleomenes III., and distinguished himself at Sellasia (222). The next eleven years he spent as a condottiere in Crete. Elected commander of the League's cavalry on his return, he reorganized that force and defeated the Aetolians on the Elean frontier (210). Appointed to the chief command two years later, he introduced heavy armour and close formation for the infantry, and with a well-trained army beat Machanidas of Sparta, near Mantinea. The new "liberator" was now so famous that Philip V. of Macedon attempted to poison him. In 202–1 Philopoemen drove Nabis, the Spartan tyrant, from Messene and routed him off Tegea. After another long sojourn in Crete he again received the command against Nabis. Though unsuccessful at sea, he almost annihilated Nabis's land force near Gythium, but was prevented by the Roman Flamininus from taking Sparta. In 190 Philopoemen protected Sparta, which meanwhile had joined the League and thereupon seceded, but punished a renewed defection so cruelly as to draw the censure of Rome upon his country. At Messene he likewise checked a revolt (189), but when that city again rebelled, in 184, he was captured in a skirmish and promptly executed. His body was recovered by the Achaeans and buried with great solemnity.

Philopoemen's great merit lies in his having restored to his compatriots that military efficiency without which the Achaean League for all its skilful diplomacy could never stand. Towards Rome he advocated a courteous but independent attitude. In politics he was a democrat, and introduced reforms of a popular character (see ACHAEAN LEAGUE).

Polybius' *Histories* (x.–xxiii.) are our chief authority. These and a special treatise on Philopoemen (now lost) were used by Plutarch (*Philopoemen*), Pausanias (viii. 49–51), Livy (xxxi.–xxxviii.), and indirectly by Justin (xxx.–xxxiv.).

PHILOPONUS, JOANNES (JOHN THE GRAMMARIAN), Greek philosopher of Alexandria, lived in the later part of the 5th and the beginning of the 6th century of our era. The surname *Grammaticus* he assumed in virtue of his lectures on language and literature; that of *Philoponus* owing to the large number of treatises he composed. He was a pupil of Ammonius Hermiae, and is supposed to have written the life of Aristotle sometimes attributed to his master. To Philoponus are attributed a large number of works on theology and philosophy. It is said that, though he was a pupil of Ammonius, he was at first a Christian, and he has been credited with the authorship of a commentary on the Mosaic Cosmogony in eight books, dedicated to Sergius, patriarch of Constantinople, and edited by Balthasar Corderius in 1630. Other authorities maintain that this, as well as the *Disputatio de paschale*, was the work of another author, John the Tritheist. It was perhaps this Philoponus who tried to save the Alexandrian library from the caliph Omar after Amu's victory in 639.

The more certain writings of Philoponus consist of commentaries on Aristotle. These include works on the *Physica*, the *Prior* and the *Posterior Analytics*, the *Meteorologica*, the *De anima*, the *De generatione animalium*, the *De generatione et interitu* and the *Metaphysica*. These have been frequently edited and are interesting in connexion with the adoption of Aristotelianism by the Christian Church. They seem to have embodied the lectures of Ammonius with additions by Philoponus, and are remarkable rather for elaborate care than for originality and insight. He wrote also an attack on Proclus (*De aeternitate mundi*). Two treatises on mathematics are ascribed to him: *A Commentary on the Mathematics of Nicomachus*, edited by Hoche (1864 and 1867), and a *Treatise on the Use of the Astrolabe*, published by Hase. The latter is the most ancient work on this instrument, and its authenticity is rendered almost certain by its reference to Ammonius as the master of the author.

PHILOSOPHY (Gr. φίλος, fond of, and σοφία, wisdom), a general term whose meaning and scope have varied very considerably according to the usage of different authors and different ages. It can best be explained by a survey of the steps by which philosophy differentiated itself, in the history of Greek thought, from the idea of knowledge and culture in general. These steps may be traced in the gradual specification of the term. The tradition which assigns the first employment of the Greek word φιλοσοφία to Pythagoras has hardly any claim to be regarded as authentic; and the somewhat self-conscious modesty to which Diogenes Laërtius attributes the choice of the designation is, in all probability, a piece of etymology crystallized into narrative. It is true that, as a matter of fact, the earliest uses of the word (the verb φιλοσοφεῖν occurs in Herodotus and Thucydides) imply the idea of the *pursuit* of knowledge; but the distinction between the σοφός, or wise man, and the φιλόσοφος, or lover of wisdom, appears first in the Platonic writings, and lends itself naturally to the so-called Socratic irony. The same thought is to be found in Xenophon, and is doubtless to be attributed to the historical Socrates. But the word soon lost this special implication. What is of real interest to us is to trace the progress from the idea of the philosopher as occupied with any and every department of knowledge to that which assigns him a special kind of knowledge as his province.

A specific sense of the word first meets us in Plato, who defines the philosopher as one who apprehends the essence or reality of things in opposition to the man who dwells in appearances and the shows of sense. The philosophers, he says, "are those who are able to grasp the eternal and immutable"; they are "those who set their affections on that which in each case really exists" (*Rep.* 480). In Plato, however, this distinction is applied chiefly in an ethical and religious direction; and, while it defines philosophy, so far correctly, as the endeavour to express what things are in their ultimate constitution, it is not yet accompanied by a sufficient differentiation of the subsidiary inquiries by which this ultimate question may be approached. Logic, ethics and physics, psychology, theory of knowledge and metaphysics are all fused together by Plato in a semi-religious synthesis. It is not till we come to Aristotle—the encyclopaedist of the ancient world—that we find a demarcation of the different philosophic disciplines corresponding, in the main, to that still current. The earliest philosophers, or "physiologers," had occupied themselves chiefly with what we may call cosmology; the one question which covers everything for them is that of the underlying substance of the world around them, and they essay to answer this question, so to speak, by simple inspection. In Socrates and Plato, on the other hand, the start is made from a consideration of man's moral and intellectual activity; but knowledge and action are confused with one another, as in the Socratic doctrine that virtue is knowledge. To this correspond the Platonic confusion of logic and ethics and the attempt to substitute a theory of concepts for a metaphysic of reality. Aristotle's methodic intellect led him to separate the different aspects of reality here confounded. He became the founder of logic, psychology, ethics and aesthetics as separate sciences; while he prefixed to all such (comparatively) special inquiries the investigation of the ultimate nature of existence as such, or of those first principles which are common to, and presupposed in, every narrower field of knowledge. For this investigation Aristotle's most usual name is "first philosophy" or, as a modern might say, "first principles"; but there has since been appropriated to it, apparently by accident, the title "metaphysics." "Philosophy," as a term of general application, was not, indeed restricted by Aristotle or his successors to the disciplines just enumerated. Aristotle himself includes under the title, besides mathematics, all his physical inquiries. It was only in the Alexandrian period, as Zeller points out, that the special sciences attained to independent cultivation. Nevertheless, as the mass of knowledge accumulated, it naturally came about that the name "philosophy" ceased to be applied to inquiries concerned with the particulars as such. The details of physics, for example, were abandoned to the scientific specialist, and philosophy restricted itself in this department to the question of the relation of the physical universe to the ultimate ground or author of things. This inquiry which was long called "rational cosmology," may be said to form part of the general subject of metaphysics, or at all events a pendant to it. By the gradual sifting out of the special sciences philosophy thus came to embrace primarily the inquiries grouped as "metaphysics" or "first philosophy." These would embrace, according to the Wolffian scheme long current in philosophical textbooks, ontology proper, or the science of being as such, with its three-branch sciences of (rational) psychology, cosmology and (rational or natural) theology, dealing with the three chief forms of being—the soul, the world and God. Subsidiary to metaphysics, as the central inquiry, stand the sciences of logic and ethics, to which may be added aesthetics, constituting three normative sciences—sciences, that is, which do not, primarily, describe facts, but rather prescribe ends or set forth ideals. It is evident, however, that if logic deals with conceptions which may be considered constitutive of knowledge as such, and if ethics deals with the harmonious realization of human life, which is the highest known form of existence, both sciences must have a great deal of weight in the settling of the general question of metaphysics.

In sum, then, we may say that "philosophy" has come to be understood at least in modern times as a general term covering the various disciplines just enumerated. It has frequently tended, however, and still tends, to be used as specially convertible with the narrower term "metaphysics." This is not unnatural, seeing that it is only so far as they bear on the one central question of the nature of existence that philosophy spreads its mantle over psychology, logic or ethics. The particular organic conditions of perception and the associative laws to which the mind, as a part of nature, is subjected, are facts in themselves indifferent to the philosopher; and therefore the development of psychology into an independent science, which took place during the latter half of the 19th century and may now be said to be complete, represents an entirely natural evolution. Similarly, logic, so far as it is an art of thought or a doctrine of fallacies, and ethics, so far as it is occupied with a natural history of impulses and moral sentiments, do neither of them belong, except by courtesy, to the philosophic province. But, although this is so, it is perhaps hardly desirable to deprive ourselves of the use of two terms instead of one. It will not be easy to infuse into so abstract and bloodless a term as "metaphysics" the fuller life (and especially the inclusion of ethical considerations) suggested by the more concrete term "philosophy."

We shall first of all, then, attempt to differentiate philosophy from the special sciences, and afterwards proceed to take up one by one what have been called the philosophical sciences, with the view of showing how far the usual subject-matter of each is really philosophical in its bearing, and how far it belongs rather to the domain of "science" strictly so called. The order in which, for clearness of exposition, it will be most convenient to consider these disciplines will be psychology, epistemology or theory of knowledge, and metaphysics, then logic, aesthetics and ethics. Finally, the connexion of the last-mentioned with politics (or, to speak more modernly, with jurisprudence and sociology), with the philosophy of history and the philosophy of religion, will call for a few words on the relation of these sciences to general philosophy.

Philosophy and Natural Science.—In distinguishing philosophy from the sciences, it may not be amiss at the outset to guard against the possible misunderstanding that philosophy is concerned with a subject-matter different from, and in some obscure way transcending, the subject-matter of the sciences. Now that psychology, or the observational and experimental study of mind, may be said to have been definitively included among the positive sciences, there is not even the apparent ground which once existed for such an idea. Philosophy, even under its most discredited name of metaphysics, has no other subject-matter than the nature of the real world, as that world lies around us in everyday life, and lies open to observers on every side. But if this is so, it may be asked what function can remain for philosophy when every portion of the field is already lotted out and enclosed by specialists? Philosophy claims to be the science of the whole; but, if we get the knowledge of the parts from the different sciences, what is there left for philosophy to tell us? To this it is sufficient to answer generally that the synthesis of the parts is something more than that detailed knowledge of the parts in separation which is gained by the man of science. It is with the ultimate synthesis that philosophy concerns itself; it has to show that the subject-matter which we are all dealing with in detail really *is* a whole, consisting of articulated members. Evidently, therefore, the relation existing between philosophy and the sciences will be, to some extent, one of reciprocal influence. The sciences may be said to furnish philosophy with its matter, but philosophical criticism reacts upon the matter thus furnished, and transforms it. Such transformation is inevitable, for the parts only exist and can only be fully, *i.e.* truly, known in their relation to the whole. A pure specialist, if such a being were possible, would be merely an instrument whose results had to be co-ordinated and used by others. Now, though a pure specialist may be an abstraction of the mind, the tendency of specialists in any department naturally is to lose sight of the whole in attention to the particular categories or modes of nature's working which happen to be exemplified, and fruitfully applied, in their own sphere of investigation; and in proportion as this is the case it becomes necessary for their theories to be co-ordinated with the results of other inquirers, and set, as it were, in the light of the whole. This task of co-ordination, in the broadest sense, is undertaken by philosophy; for the philosopher is essentially what Plato, in a happy moment, styled him, *συνοπτικός*, the man who takes a "synoptic" or comprehensive view of the universe as a whole. The aim of philosophy (whether fully attainable or not) is to exhibit the universe as a rational system in the harmony of all its parts; and accordingly the philosopher refuses to consider the parts out of their relation to the whole whose parts they are. Philosophy corrects in this way the abstractions which are inevitably made by the scientific specialist, and may claim, therefore, to be the only "concrete" science, that is to say, the only science which takes account of all the elements in the problem, and the only science whose results can claim to be true in more than a provisional sense.

For it is evident from what has been said that the way in which we commonly speak of "facts" is calculated to convey a false impression. The world is not a collection of individual facts existing side by side and capable of being known separately. A fact is nothing except in its relations to other facts; and as these relations are multiplied in the progress of knowledge the nature of the so-called fact is indefinitely modified. Moreover, every statement of fact involves certain general notions and theories, so that the "facts" of the separate sciences cannot be stated except in terms of the conceptions or hypotheses which are assumed by the particular science. Thus mathematics assumes space as an existent infinite, without investigating in what sense the existence or the infinity of this *Unding*, as Kant called it, can be asserted. In the same way, physics may be said to assume the notion of material atoms and forces. These and similar assumptions are ultimate presuppositions or working hypotheses for the sciences themselves. But it is the office of philosophy, as a theory of knowledge, to submit such conceptions to a critical analysis, with a view to discover how far they can be *thought out*, or how far, when this is done, they refute themselves, and call for a different form of statement, if they are to be taken as a statement of the ultimate nature of the real.[1] The first statement may frequently turn out to have been merely provisionally or relatively true; it is then superseded by, or rather inevitably merges itself in, a less abstract account. In this the same "facts" appear differently, because no longer separated from other aspects that belong to the full reality of the known world. There is no such thing, we have said, as an individual fact; and the nature of any fact is not fully known unless we know it in all its relations to the system of the universe, or, in Spinoza's phrase, *sub specie aeternitatis*. In strictness, there is but one *res completa* or concrete fact, and it is the business of philosophy, as science of the whole, to expound the chief relations that constitute its complex nature.

The last abstraction which it becomes the duty of philosophy to remove is the abstraction from the knowing subject which is made by all the sciences, including, as we shall see, the science of psychology. The sciences, one and all, deal with a world of objects, but the ultimate fact as we know it is the existence of an object for a subject. Subject-object, knowledge, or, more widely, self-consciousness with its implicates—this unity in duality is the ultimate aspect which reality presents. It has generally been considered, therefore, as constituting in a special sense the problem of philosophy. Philosophy may be said to be the explication of what is involved in this relation, or, in Kantian phraseology, a theory of its possibility. Any would-be theory of the universe which makes its central fact impossible stands self-condemned. On the other hand, a sufficient analysis here may be expected to yield us a statement of the reality of things *in its last terms*, and thus to shed a light backwards upon the true nature of our subordinate conceptions.

Psychology, Epistemology and Metaphysics.—This leads to the consideration of the main divisions of philosophy—Psychology (*q.v.*), epistemology (theory of knowledge, *Erkenntnisstheorie*), and metaphysics (ontology; see Metaphysic). A special relation has always existed between psychology and systematic philosophy, but the closeness of the connexion has been characteristic of modern and more particularly of English thought. The connexion is not difficult to explain, seeing that in psychology, or the science of mind, we study the fact of intelligence (and moral action), and have, so far, in our hands the fact to which all other facts are relative. From this point of view we may even see a truth in Jacobi's dictum as quoted by Sir W. Hamilton: "Nature conceals God; man reveals God." Nature by itself, that is to say, is insufficient. The ultimate explanation of things cannot be given by any theory which excludes from its survey the intelligence in which nature, as it were, gathers herself up. But knowledge, or the mind as knowing, willing, &c., may be looked at in two different ways. It may be regarded simply as a fact; in which case the evolutions of mind may be traced and reduced to laws in the same way as the phenomena treated by the other sciences. This study gives us the science of empirical psychology, or, as it is now termed, psychology *sans phrase*. In order to give an adequate account of its subject-matter, psychology may require higher or more complex categories than are employed in the other sciences, just as biology, for example, cannot work with mechanical categories alone, but introduces the conception of development or growth. But the affinities of such a study are manifestly with the sciences as such rather than with philosophy; and the definitive establishment of psychology as an independent science has already been alluded to. Since it has been taken up by specialists, psychology is being established on a broader basis of induction, and with the advantage, in some departments, of the employment of experimental methods of measurement. But it is not of mind in this aspect

[1] The revisional office which philosophy here assumes constitutes her the critic of the sciences. It is in this connexion that the meaning of the definition of philosophy as "the science of principles" can best be seen. This is perhaps the most usual definition, and, though vague, one of the least misleading.

that such assertions can be made as those quoted above, "Mind, as studied by the psychologist—mind as a mere fact or phenomenon—grounds no inference to anything beyond itself." The distinction between mind viewed as a succession of "states of consciousness" and the further aspect of mind which philosophy considers was very clearly put by Croom Robertson, who also made a happy suggestion of two terms to designate the double point of view:—

"We may view knowledge as mere subjective function, but it has its full meaning only as it is taken to represent what we may call objective fact, or is such as is named (in different circumstances) real, valid, true. As mere subjective function, which it is to the psychologist, it is best spoken of by an unambiguous name, and for this there seems none better than Intellection. We may then say that psychology is occupied with the natural function of *Intellection*, seeking to discover its laws and distinguishing its various modes (perception, representative imagination, conception, &c.) according to the various circumstances in which the laws are found at work. Philosophy, on the other hand, is theory of *Knowledge* (as that which is known)."—"Psychology and Philosophy," *Mind* (1883), pp. 15, 16.

The confusion of these two points of view has led, and still leads, to serious philosophical misconception. It is hardly an exaggeration to say that, in the English school since Hume, psychology superseded properly philosophical inquiry. And we find even a thinker with a wider horizon like Sir W. Hamilton encouraging the confusion by speaking of "psychology *or* metaphysics,"[1] while his lectures on metaphysics are mainly taken up with what belongs in the strictest sense to psychology proper, with an occasional excursus (as in the theory of perception) into epistemology. The distinction between psychology and theory of knowledge was first clearly made by Kant, who repeatedly insisted that the *Critique of Pure Reason* was not to be taken as a psychological inquiry. He defined his problem as the *quid juris* or the question of the validity of knowledge, not its *quid facti* or the laws of the empirical genesis and evolution of intellection (to use Croom Robertson's phraseology). Since Kant philosophy has chiefly taken the form of theory of knowledge or of a criticism of experience. Not, indeed, a preliminary criticism of our faculties or conceptions such as Kant himself proposed to institute, in order to determine the limits of their application; such a criticism *ab extra* of the nature of our experience is essentially a thing impossible. The only criticism which can be applied in such a case is the immanent criticism which the conceptions or categories exercise upon one another. The organized criticism of these conceptions is really nothing more than the full explication of what they mean and of what experience in its full nature or notion is. This constitutes the theory of knowledge in the only tenable sense of the term, and it lays down, in Kantian language, the conditions of the possibility of experience. These conditions are the conditions of knowledge as such, or, as it may be put, of objective consciousness—of a self-consciousness of a world of objects and through them conscious of itself. The inquiry is, therefore, logical or transcendental in its nature, and does not entangle us in any decision as to the conditions of the genesis of such consciousness in the individual. When we inquire into subjective conditions we are thinking of facts causing other facts. But the logical or transcendental conditions are not causes or even factors of knowledge; they are the statement of its idea. Hence the dispute between evolutionist and transcendentalist rests, in general, on an *ignoratio elenchi*; for the history of the genesis of an idea (the historical or genetic method) does not contain an answer to—though it may throw light on—the philosophical question of its truth or validity. Speaking of this transcendental consciousness, Kant goes so far as to say that it is not of the slightest consequence "whether the idea of it be clear or obscure (in empirical consciousness), no, not even whether it really exists or not. But the possibility of the logical form of all knowledge rests on its relation to this apperception as a faculty or potentiality" (*Werke*, ed. Hartenstein, iii. 578 note). Or, if we return to the distinction between epistemology and psychology, by way of illustrating the nature of the former, we may take the following summing up by Professor James Ward in a valuable article on "Psychological Principles" in *Mind* (April 1883, pp. 166, 167): "Comparing psychology and epistemology, then, we may say that the former is essentially genetic in its method, and might, if we had the power to revise our existing terminology, be called biology; the latter, on the other hand, is essentially devoid of everything historical, and treats, *sub specie aeternitatis*, as Spinoza might have said, of human knowledge, conceived as the possession of mind in general."

Kant's problem is not, in its wording, very different from that which Locke set before him when he resolved to "inquire into the original, certainty and extent of human knowledge together with the grounds and degrees of belief, opinion and assent." Locke's *Essay* is undoubtedly, in its intention, a contribution to the theory of knowledge. But, because time had not yet made the matter clear, Locke suffered himself to digress in his second book into the psychological question of the origin of our ideas; and his theory of knowledge is ruined by the failure to distinguish between the epistemological sense of "idea" as significant content and the psychological sense in which it is applied to a fact or process in the individual mind. The same confusion runs through Berkeley's arguments and vitiates his conclusions as well as those of Hume. But appearing with these thinkers as the problem of perception, epistemology widens its scope and becomes, in Kant's hands, the question of the possibility of experience in general. With Hegel it passes into a completely articulated "logic," which apparently claims to be at the same time a metaphysic, or an ultimate expression of the nature of the real.

This introduces us to the second part of the question we are seeking to determine, namely the relation of epistemology to metaphysics. It is evident that philosophy as theory of knowledge must have for its complement philosophy as metaphysics (ontology) or theory of being. The question of the truth of our knowledge, and the question of the ultimate nature of what we know, are in reality two sides of the same inquiry; and therefore our epistemological results have to be ontologically expressed. But it is not every thinker that can see his way with Hegel to assert in set terms the identity of thought and being. Hence the theory of knowledge becomes with some a theory of human ignorance. This is the case with Herbert Spencer's doctrine of the Unknowable, which he advances as the result of epistemological considerations in the philosophical prolegomena to his system. Very similar positions were maintained by Kant and Comte; and, under the name of "agnosticism" (*q.v.*), the theory has popularized itself in the outer courts of philosophy, and on the shifting borderland of philosophy and literature. The truth is that the habit of thinking exclusively from the standpoint of the theory of knowledge tends to beget an undue subjectivity of temper. And the fact that it has become usual for men to think from this standpoint is very plainly seen in the almost universal description of philosophy as an analysis of "experience," instead of its more old-fashioned designation as an inquiry into "the nature of things." As it is matter of universal agreement that the problem of being must be attacked indirectly through the problem of knowledge, this substitution may be regarded as an advance; more especially as it implies that the fact of experience, or of self-conscious existence, is the chief fact to be dealt with. But if so, then self-consciousness must be treated as itself real, and as organically related to the rest of existence. If self-consciousness be treated in this objective fashion, then we pass naturally from epistemology to metaphysics or ontology. (For, although the term "ontology" has been as good as disused, it still remains true that the aim of philosophy must be to furnish us with an ontology or a coherent and adequate theory of the nature of reality.) But if, on the other hand, knowledge and reality be *ab initio* opposed to one another—if consciousness be set on one side as over against reality, and merely holding up a mirror to it—then it follows with equal naturalness that the truly real must be something which lurks unrevealed

[1] It is true that he afterwards modifies this misleading identification by introducing the distinction between empirical psychology or the phenomenology of mind and inferential psychology or ontology, *i.e.* metaphysics proper. But he continues to use the terms "philosophy," "metaphysics," and "mental science" as synonymous.

behind the subject's representation of it. Hence come the different varieties of a so-called phenomenalism. The upholders of such a theory would, in general, deride the term "metaphysics" or "ontology"; but it is evident, none the less, that their position itself implies a certain theory of the universe and of our own place in it, and the establishment of this theory constitutes their metaphysics.

Without prejudice, then, to the claim of epistemology to constitute the central philosophic discipline, we may simply note its liability to be pressed too far. The exclusive preoccupation of men's minds with the question of knowledge during the neo-Kantian revival in the 'seventies of the last century drew from Lotze the caustic criticism that "the continual sharpening of the knife becomes tiresome, if, after all, we have nothing to cut with it." Stillingfleet's complaint against Locke was that he was "one of the gentlemen of this new way of reasoning that have almost discarded substance out of the reasonable part of the world." The same may be said with greater truth of the devotees of the theory of knowledge; they seem to have no need of so old-fashioned a commodity as reality. Yet, after all, Fichte's dictum holds good that knowledge *as* knowledge—*i.e.* so long as it is looked at as knowledge—is, *ipso facto*, *not* reality. The result of the foregoing, however, is to show that, as soon as epistemology draws its conclusion, it becomes metaphysics; the theory of knowledge passes into a theory of being. The ontological conclusion, moreover, is not to be regarded as something added by an external process; it is an immediate implication. The metaphysic is the epistemology from another point of view—regarded as completing itself, and explaining in the course of its exposition that relative or practical separation of the individual knower from the knowable world, which it is a sheer assumption to take as absolute. This, not the so-called assumption of the implicit unity of being and thought, is the really unwarrantable postulate; for it is an assumption which we are obliged to retract bit by bit, while the other offers the whole doctrine of knowledge as its voucher.

Logic, Aesthetics and Ethics.—If the theory of knowledge thus passes insensibly into metaphysics it becomes somewhat difficult to assign a distinct sphere to logic (*q.v.*). Ueberweg's definition of it as "the science of the regulative laws of thought" (or "the normative science of thought") comes near enough to the traditional sense to enable us to compare profitably the usual subject-matter of the science with the definition and end of philosophy. The introduction of the term "regulative" or "normative" is intended to differentiate the science from psychology as the science of mental processes or events. In this reference logic does not tell us how our intellections connect themselves as mental phenomena, but how we ought to connect our thoughts if they are to realize truth (either as consistency with what we thought before or as agreement with observed facts). Logic, therefore, agrees with epistemology (and differs from psychology) in treating thought not as mental fact but as knowledge, as idea, as having meaning in relation to an objective world. To this extent it must inevitably form a part of the theory of knowledge. But, if we desire to keep by older landmarks and maintain a distinction between the two disciplines, a ground for doing so may be found in the fact that all the main definitions of logic point to the investigation of the laws of thought in a subjective reference—with a view, that is, by an analysis of the operation, to ensure its more correct performance. According to the old phrase, logic is the art of correct thinking. Moreover, we commonly find the logician assuming that the process of thought has advanced a certain length before his examination of it begins; he takes his material full-formed from perception, without, as a rule, inquiring into the nature of the conceptions which are involved in our perceptive experience. Occupying a position, therefore, within the wider sphere of the general theory of knowledge, ordinary logic consists in an analysis of the nature of general statement, and of the conditions under which we pass validly from one general statement to another. But the logic of the schools is eked out by contributions from a variety of sources (*e.g.* from grammar on one side and from psychology on another), and cannot claim the unity of an independent science.

Aesthetics (*q.v.*) may be treated as a department of psychology or physiology, and in England this is the mode of treatment that has been most general. To what peculiar excitation of our bodily or mental organism, it is asked, are the emotions due which make us declare an object beautiful or sublime? And, the question being put in this form, the attempt has been made in some cases to explain away any peculiarity in the emotions by analysing them into simpler elements, such as primitive organic pleasures and prolonged associations of usefulness or fitness. But, just as psychology in general cannot do duty for a theory of knowledge, so it holds true of this particular application of psychology that a mere reference of these emotions to the mechanism and interactive play of our faculties cannot be regarded as an account of the nature of the beautiful. Perhaps by talking of "emotions" we tend to give an unduly subjective colour to the investigation; it would be better to speak of the *perception* of the beautiful. Pleasure in itself is unqualified, and affords no differentia. In the case of a beautiful object the resultant pleasure borrows its specific quality from the presence of determinations essentially objective in their nature, though not reducible to the categories of science. Unless, indeed, we conceive our faculties to be constructed on some arbitrary plan which puts them out of relation to the facts with which they have to deal, we have a prima facie right to treat beauty as an objective determination of things. The question of aesthetics would then be formulated—What is it in things that makes them beautiful, and what is the relation of this aspect of the universe to its ultimate nature, as that is expounded in metaphysics? The answer constitutes the substance of aesthetics, considered as a branch of philosophy. But it is not given simply in abstract terms: the philosophical treatment of aesthetics includes also an exposition of the concrete phases of art, as these have appeared in the history of the world, relating themselves to different phases of human culture.

Of ethics (*q.v.*) it may also be said that many of the topics commonly embraced under that title are not strictly philosophical in their nature. They are subjects for a scientific psychology, employing the historical method with the conceptions of heredity and development, and calling to its aid, as such a psychology will do, the investigations of all the sociological sciences. To such a psychology must be relegated all questions as to the origin and development of moral ideas. Similarly, the question debated at such length by English moralists as to the nature of the moral faculty (moral sense, conscience, &c.) and the controversy concerning the freedom of the will belong entirely to psychology. If we exclude such questions in the interest of systematic correctness, and seek to determine for ethics a definite subject-matter, the science may be said to fall into two departments. The first of these deals with the notion of duty, and endeavours to define the good or the ultimate end of action; the second lays out the scheme of concrete duties which are deducible from, or which, at least, are covered by, this abstractly stated principle. The second of these departments is really the proper subject-matter of ethics considered as a separate science; but it is often conspicuous by its absence from ethical treatises. However moralists may differ on first principles, there seems to be remarkably little practical divergence when they come to lay down the particular laws of morality. It may be added that, where a systematic account of duties is actually given, the connexion of the particular duties with the universal formula is in general more formal than real. It is only under the head of casuistry (*q.v.*) that ethics has been much cultivated as a separate science. The first department of ethics, on the other hand, is the branch of the subject in virtue of which ethics forms part of philosophy. As described above, it ought rather to be called, in Kant's phrase, the metaphysic of ethics. A theory of obligation is ultimately found to be inseparable from a metaphysic of personality. The connexion of ethics with metaphysics will be patent as a matter of fact, if it be remembered how Plato's philosophy is summed up in the idea of the good, and how

Aristotle also employs the essentially ethical notion of end as the ultimate category by which the universe may be explained or reduced to unity. But the necessity of the connexion is also apparent, unless we are to suppose that, as regards the course of universal nature, man is altogether an *imperium in imperio*, or rather (to adopt the forcible phrase of Marcus Aurelius) an abscess or excrescence on the nature of things. If, on the contrary, we must hold that man is essentially related to what the same writer calls "a common nature," then it is a legitimate corollary that in man as intelligence we ought to find the key of the whole fabric. At all events, this method of approach must be truer than any which, by restricting itself to the external aspect of phenomena as presented in space, leaves no scope for inwardness and life and all that, in Lotze's language, gives "value" to the world. The argument *ex analogia hominis* has often been carried too far; but if a "chief end of man" be discoverable—ἀνθρώπινον ἀγαθόν, as Aristotle wisely insisted that the ethical end must be determined—then it may be assumed that this end cannot be irrelevant to that ultimate "meaning" of the universe which, according to Lotze, is the quest of philosophy. If "the idea of humanity," as Kant called it, has ethical perfection at its core, then a universe which is really an organic whole must be ultimately representable as a moral order or a spiritual kingdom such as Leibnitz named, in words borrowed from St Augustine, a city of God.

Philosophy of the State (Political Philosophy), Philosophy of History, Philosophy of Religion.—In Plato and Aristotle ethics and politics are indissolubly connected. In other words, seeing that the highest human good is realizable only in a community, the theory of the state as the organ of morality, and itself in its structure and institutions the expression of ethical ideas or qualities, becomes an integral part of philosophy. The difficulty already hinted at, which individualistic systems of ethics experience in connecting particular duties with the abstract principle of duty is a proof of the failure of their method. For the content of morality we are necessarily referred, in great part, to the experience crystallized in laws and institutions and to the unwritten law of custom, honour and good breeding, which has become organic in the society of which we are members. Plato's *Republic* and Hegel's *Philosophie des Rechts* are the most typical examples of a fully developed philosophy of the state, but in the earlier modern period the prolonged discussion of natural rights and the social contract must be regarded as a contribution to such a theory. Moreover, if philosophy is to complete its constructive work, it must bring the course of human history within its survey, and exhibit the sequence of events as an evolution in which the purposive action of reason is traceable. This is the task of the philosophy of history, a peculiarly modern study, due to the growth of a humanistic and historical point of view. Lessing's conception of history as an "education of the human race" is a typical example of this interpretation of the facts, and was indeed the precursor which stimulated many more elaborate German theories. The philosophy of history differs, it will be observed, from the purely scientific or descriptive studies covered by the general title of sociology. Sociology conceives itself as a natural science elucidating a factual sequence. The philosophy of history is essentially teleological; that is to say, it seeks to interpret the process as the realization of an immanent end. It may be said, therefore, to involve a complete metaphysical theory. Social institutions and customs and the different forms of state-organization are judged according to the degree in which they promote the realization of the human ideal. History is thus represented by Hegel, for example, as the realization of the idea of freedom, or rather as the reconciliation of individual freedom and the play of cultured interests with the stable objectivity of law and an abiding consciousness of the greater whole in which we move. So far as the course of universal history can be truly represented as an approximation to this reconciliation by a widening and deepening of both the elements, we may claim to possess a philosophy of history; and although the possibility of such a philosophy seems implied in the postulated rationality of the universe, many would hold that it remains as yet an unachieved ideal.

There only remains to be briefly noticed the relation of philosophy to theology and the nature of what is called Philosophy of Religion. By theology is commonly understood the systematic presentation of the teaching of some positive or historical religion as to the existence and attributes of a Supreme Being, including his relation to the world and especially to man. But these topics have also been treated by philosophers and religious thinkers, without dependence on any historical data or special divine revelation, under the title of Natural Theology. Natural Theology is specially associated with the Stoic theories of providence in ancient times and with elaborations of the argument from design in the 18th century. But there is no warrant for restricting the term to any special mode of approaching the problems indicated; and as these form the central subject of metaphysical inquiry, no valid distinction can be drawn between natural theology and general metaphysics. The philosophy of religion, on the other hand, investigates the nature of the religious consciousness and the value of its pronouncements on human life and man's relation to the ground of things. Unity, reconciliation, peace, joy, "the victory that overcometh the world"—such, in slightly varying phrases, is the content of religious faith. Does this consciousness represent an authentic insight into ultimate fact, or is it a pitiful illusion of the nerves, born of man's hopes and fears and of his fundamental ignorance? The philosophy of religion assumes the first alternative. The function of philosophy in general is the reflective analysis of experience, and the religious experience of mankind is prima facie entitled to the same consideration as any other form of conscious activity. The certainties of religious faith are matter of feeling or immediate assurance, and are expressed in the pictorial language of imagination. It becomes the function of philosophy, dealing with these utterances, to relate them to the results of other spheres of experience, and to determine their real meaning in the more exact terms of thought. The philosophy of religion also traces in the different historical forms of religious belief and practice the gradual evolution of what it takes to be the truth of the matter. Such an account may be distinguished from what is usually called the science of religion by the teleological or metaphysical presuppositions it involves. The science of religion gives a purely historical and comparative account of the various manifestations of the religious instinct without pronouncing on their relative truth or value and without, therefore, professing to apply the idea of evolution in the philosophical sense. That idea is fundamental in the philosophy of religion, which therefore can be written only from the standpoint of a constructive metaphysical theory.

It is, indeed, only from the standpoint of such a theory that the definitions and divisions of the different philosophical disciplines adopted in this article can be said to hold good. But those who, like the positivists, agnostics and sceptics, deny the possibility of metaphysics as a theory of the ultimate nature of things, are still obliged to retain philosophy as a theory of knowledge, in order to justify the asserted limitation or impotence of human reason.

Bibliography.—The best general histories of philosophy are by J. E. Erdmann, Friedrich Ueberweg and W. Windelband, Windelband's being probably the freshest in its treatment and point of view. Ed. Zeller's *History of Greek Philosophy* still holds the field as the best continuous exposition of the subject, but more recent work in the early period is represented by H. Diels and J. Burnet, while Zeller's view of Plato may be said to have been superseded by the later researches of Lewis Campbell, H. Jackson and others. T. Gomperz's *Greek Thinkers* is an able, if somewhat diffuse, survey of the philosophical development in connexion with the general movement of Greek life and culture. It does not go beyond Plato. B. Hauréau, A. Stöckl and Karl Werner give the fullest and most trustworthy histories of the mediaeval period, but the subject is very carefully treated by Erdmann and Ueberweg, and a useful compendium, written from a Roman Catholic standpoint, is De Wulf's *History of Mediaeval Philosophy* (1900; Eng. trans., 1907). For modern times, in addition to the general histories already named, the works of Kuno Fischer, R. Falckenberg and H. Höffding, and R. Adamson

may be specially mentioned. Writers on the history of philosophy generally prefix to their work a discussion of the scope of philosophy, its divisions and its relations to other departments of knowledge, and the account given by Windelband and Ueberweg will be found specially good. The Introductions to Philosophy published by F. Paulsen, O. Külpe, W. Wundt and G. T. Ladd, deal largely with this subject, which is also treated by Henry Sidgwick in his *Philosophy, its Scope and Relations* (1902), by Ernest Naville, *La Définition de la philosophie* (1894) and by Wundt in the introduction to his *System der Philosophie* (1889). A useful work of general reference is J. M. Baldwin's *Dictionary of Philosophy and Psychology* (3 vols., 1902–1905). (A. S. P.-P.)

PHILOSTRATUS, the name of several, three (or four), Greek sophists of the Roman imperial period—(1) Philostratus "the Athenian" (*c.* 170–245), (2) his nephew (?) Philostratus "of Lemnos" (born *c.* 190); (3) a grandson (?) of (2). Of these the most famous is Philostratus "the Athenian," author of the *Life of Apollonius Tyana*, which he dedicated to Julia Domna, wife of Alexander Severus and mother of Caracalla (see APOLLONIUS OF TYANA).[1] He wrote also Βίοι Σοφιστῶν (*Lives of the Sophists*), *Gymnasticus* and *Epistolae* (mainly of an erotic character). Very little is known of his career. Even his name is doubtful. The *Lives of the Sophists* gives the praenomen Flavius, which, however, is found elsewhere only in Tzetzes. Eunapius and Synesius call him a Lemnian; Photius a Tyrian; his letters refer to him as an Athenian. It is probable that he was born in Lemnos, studied and taught at Athens, and then settled in Rome (where he would naturally be called *atheniensis*) as a member of the learned circle with which Julia Domna surrounded herself. He was born probably in 172, and is said by Suidas to have been living in the reign of Philip (244–249). The fact that the author of *Apollonius* is also the author of the *Lives of the Sophists* is confirmed by internal evidence. The latter is dedicated to a consul Antonius Gordianus, perhaps one of the two Gordians who were killed in 238. The work is divided into two parts: the first dealing with the ancient Sophists, *e.g.* Gorgias, the second with the later school, *e.g.* Herodes Atticus.

The *Lives* are not in the true sense biographical, but rather picturesque impressions of leading representatives of an attitude of mind full of curiosity, alert and versatile, but lacking scientific method, preferring the external excellence of style and manner to the solid achievements of serious writing. The philosopher, as he says, investigates truth; the sophist embellishes it, and takes it for granted. The *Gymnasticus* contains interesting matter concerning the Olympic games and athletic contests generally. The *Letters* breathe the spirit of the New Comedy and the Alexandrine poets; portions of *Letter* 33 are almost literally translated in Ben Jonson's *Song to Celia*, "Drink to me only with thine eyes." The Ἡρωικός, formerly attributed to Philostratus the Athenian, is probably the work of Philostratus the Lemnian. It is a popular disquisition on the heroes of the Trojan War in the form of a conversation between a Thracian vine-dresser on the shore of the Hellespont and a Phoenician merchant who derives his knowledge from the hero Protesilaus. Palamedes is exalted at the expense of Odysseus, and Homer's unfairness to him is attacked. It has been suggested that Philostratus is here describing a series of heroic paintings in the palace of Julia Domna. His other work is the Εἰκόνες (*Imagines*), ostensibly a description of 64 pictures in a Neapolitan gallery. Goethe, Welcker, Brunn, E. Bertrand and Helbig, among others, have held that the descriptions are of actually existing works of art, while Heyne and Friederichs deny this. In any case they are interesting as showing the way in which ancient artists treated mythological and other subjects, and are written with artistic knowledge and in attractive language. This work is imitated by the third Philostratus (or by some later sophist) of whose descriptions of pictures 17 remain.

There is great difficulty, due to a confused statement of Suidas, in disentangling the works and even the personalities of these Philostrati. Reference is there made to Philostratus as the son of Verus, a rhetorician in Nero's time, who wrote tragedies, comedies and treatises. Suidas thus appears to give to Philostratus the Athenian a life of 200 years! We must be content to assume two Lemnian Philostrati, both sophists, living in Rome. See further a full discussion by K. Münscher, in *Philologus* (1907), suppl. x., pp. 469–557.

Of works bearing the name Philostratus there is a collected edition by C. F. Kayser (Zürich, 1844; Leipzig, 1870–1871), and another by Westermann (Paris, 1849), with Latin translation; these supersede those by F. Morel (Paris, 1608) and Olearius (Leipzig, 1709). There are separate editions of the *Eikones* by Schenkl and Reisch (Leipzig, 1902); of the *Gymnasticus* by Mynas (1858), who discovered the MS., Daremberg (Paris, 1858), Volckmar (Aurich, 1862), and especially Julius Jüthner (1909), with introd., comments and Ger. trans.; of 73 epistles by Boissonade (Paris, 1842). The *Life of Apollonius* was first published by Aldus (1502); a French translation by Blaise de Vigenere appeared in 1596; an English translation of the first two books was published in London (1680) by Charles Blount, with some notes by Lord Herbert of Cherbury (prohibited in England in 1693, it was reprinted on the Continent); a full translation appeared in 1903. Critical works on the *Eikones* are numerous: K. Friederichs, *Die Philostratischen Bilder* (1860); Goethe, "Philostrats Gemälde" in *Complete Works* (ed. Stuttgart, 1879); Brunn, *Die Philostratischen Bilder* (1860); A. Bougot, *Une Galerie antique* (1881); E. Bertrand, *Un Critique d'art dans l'antiquité: Philostrate et son école* (1882); Bergk, "Die Philostrate" in *Fünf Abhandlungen zur Geschichte der griechischen Philosophie und Astronomie* (1883); Schmid, *Atticismus*, iv. 7, on the attribution of the works.

[1] As Lemnos was an Athenian island, any Lemnian could be called an Athenian.

PHILOXENUS, of Cythera (435–380 B.C.), Greek dithyrambic poet. On the conquest of the island by the Athenians he was taken as a prisoner of war to Athens, where he came into the possession of the dithyrambic poet Melanippides, who educated him and set him free. Philoxenus afterwards resided in Sicily, at the court of Dionysius, tyrant of Syracuse, whose bad verses he declined to praise, and was in consequence sent to work in the quarries. After leaving Sicily he travelled in Greece, Italy and Asia, reciting his poems, and died at Ephesus. According to Suidas, Philoxenus composed twenty-four dithyrambs and a lyric poem on the genealogy of the Aeacidae. In his hands the dithyramb seems to have been a sort of comic opera, and the music, composed by himself, of a debased character. His masterpiece was the *Cyclops*, a pastoral burlesque on the love of the Cyclops for the fair Galatea, written to avenge himself upon Dionysius, who was wholly or partially blind of one eye. It was parodied by Aristophanes in the *Plutus* (290). Another work of Philoxenus (sometimes attributed to Philoxenus of Leucas, a notorious parasite and glutton) is the Δεῖπνον (Dinner), of which considerable fragments have been preserved by Athenaeus. This is an elaborate bill of fare in verse, probably intended as a satire on the luxury of the Sicilian court. The great popularity of Philoxenus is attested by a complimentary resolution passed by the Athenian senate in 393. The comic poet Antiphanes spoke of him as a god among men; Alexander the Great had his poems sent to him in Asia; the Alexandrian grammarians received him into the canon; and down to the time of Polybius his works were regularly learned and annually acted by the Arcadian youth.

Fragments, with life, by G. Bippart (1843); T. Bergk, *Poetae lyrici graeci*.

PHILOXENUS (Syriac, Aksĕnāyā), of Mabbōg, one of the best of Syriac prose writers, and a vehement champion of Monophysite doctrine in the end of the 5th and beginning of the 6th centuries. He was born, probably in the third quarter of the 5th century, at Tahal, a village in the district of Bēth Garmai east of the Tigris. He was thus by birth a subject of Persia, but all his active life of which we have any record was passed in the territory of the Greek Empire. The statements that he had been a slave and was never baptized appear to be malicious inventions of his theological opponents. He was educated at Edessa, perhaps in the famous "school of the Persians," which was afterwards (in 489) expelled from Edessa[1] on account of its connexion with the Nestorian heresy. The years which followed the Council of Chalcedon (451) were a stormy period in the Syrian Church. Philoxenus soon attracted notice by his strenuous advocacy of Monophysite doctrine, and on the expulsion of Calandio (the orthodox patriarch of Antioch) in 485 was ordained bishop of Mabbōg[2] by his Monophysite successor Peter the Fuller (Barhebraeus, *Chron. eccl.* i. 183). It was probably during the earlier years of his episcopate that Philoxenus composed his thirteen homilies on the Christian life. Later he devoted himself to the revision of the Syriac version of the Bible, and with the help of his chorepiscopus Polycarp produced in 508 the so-called Philoxenian version, which was in some sense the received Bible of the Monophysites during the 6th century. Meantime he continued his ecclesiastical activity, working as a bitter opponent of

[1] According to Barhebraeus (*Chron. eccl.* ii. 55) through the efforts of Philoxenus himself.

[2] Hierapolis of the Greeks, Manbij of the Arabs, a few miles west of the Euphrates about latitude 36½°.

Flavian II., who had accepted the decrees of the Council of Chalcedon and was patriarch of Antioch from 498 to 512. The Monophysites had the sympathy of the emperor Anastasius, and were finally successful in ousting Flavian in 512 and replacing him by their partisan Severus. Of Philoxenus's part in the struggle we possess not too trustworthy accounts by hostile writers, such as Theophanes and Theodorus Lector. We know that in 498 he was staying at Edessa[1]; in or about 507, according to Theophanes, he was summoned by the emperor to Constantinople; and he finally presided at a synod at Sidon which was the means of procuring the replacement of Flavian by Severus. But the triumph was short-lived. Justin I., who succeeded Anastasius in 518, was less favourable to the party of Severus and Philoxenus, and in 519 they were both sentenced to banishment. Philoxenus was sent to Philippopolis in Thrace, and afterwards to Gangra in Paphlagonia, where he met his death by foul play in 523.

Apart from his redoubtable powers as a controversialist, Philoxenus deserves commemoration as a scholar, an elegant writer, and an exponent of practical Christianity. Of the chief monument of his scholarship—the Philoxenian version of the Bible—only the Gospels and certain portions of Isaiah are known to survive (see Wright, *Syr. Lit.* 14). It was an attempt to provide a more accurate rendering of the Greek Bible than had hitherto existed in Syriac, and obtained recognition among the Monophysites until superseded by the still more literal renderings of the Old Testament by Paul of Tella and of the New Testament by Thomas of Harkel (both in 616–617), of which the latter at least was based on the work of Philoxenus. There are also extant portions of commentaries on the Gospels from his pen. Of the excellence of his style and of his practical religious zeal we are able to judge from the thirteen homilies on the Christian life and character which have been edited and translated by Budge (London, 1894). In these he holds aloof for the most part from theological controversy, and treats in an admirable tone and spirit the themes of faith, simplicity, the fear of God, poverty, greed, abstinence and unchastity. His affinity with his earlier countryman, Aphraates is manifest both in his choice of subjects and his manner of treatment. As his quotations from Scripture appear to be made from the Peshitta, he probably wrote the homilies before he embarked upon the Philoxenian version.[2] Philoxenus wrote also many controversial works and some liturgical pieces. Many of his letters survive, and at least two have been edited.[3] Several of his writings were translated into Arabic and Ethiopic. (N. M.)

PHILTRE (Lat. *philtrum*, from Gr. φίλτρον, φιλεῖν, to love), a drug or other medicinal drink supposed to have the magical property of exciting love.

PHINEUS, in Greek legend, son of Agenor, the blind king of Salmydessus on the coast of Thrace. He was skilled in the art of navigation, and Apollo had bestowed upon him the gift of prophecy. His blindness was a punishment from the gods for his having revealed the counsels of Zeus to mortals, or for his treatment of his sons by his first wife Cleopatra. His second wife having accused her stepsons of dishonourable proposals, Phineus put out their eyes, or exposed them to the wild beasts, or buried them in the ground up to their waists and ordered them to be scourged. Zeus offered him the choice of death or blindness; Phineus chose the latter, whereupon Helios (the sun-god), offended at the slight thus put upon him, sent the Harpies to torment him. In another story, the Argonauts (amongst whom were Calais and Zetes, the brothers of Cleopatra), on their arrival in Thrace found the sons of Phineus half-buried in the earth and demanded their liberation. Phineus refused and a fight took place in which he was slain by Heracles, who freed Cleopatra (who had been thrown into prison) and her sons, and reinstated them as rulers of the kingdom. Tragedies on the subject of Phineus were written by Aeschylus and Sophocles. These would directly appeal to an Athenian audience, Phineus's first wife having been the daughter of Orithyia (daughter of Erechtheus, king of Athens), who had been carried off by Boreas to his home in Thrace. The punishment of Phineus would naturally be regarded as a just retribution for the insult put upon a princess of the royal house of Athens.

Apollodorus i. 9, 21, iii. 15, 3; Sophocles, *Antigone*, 966, with Jebb's notes; Diod. Sic. iv. 43, 44; Servius on *Aeneid* iii. 209; Schol. on Apollonius Rhodius ii. 178.

PHIPS (or Phipps), **SIR WILLIAM** (1651–1695), colonial governor of Massachusetts, was born on the 2nd of February 1651, at Woolwich, Maine, near the mouth of the Kennebec river. He was a shepherd until he was eighteen, and then a ship carpenter's apprentice for four years; worked at his trade in Boston for a year, at this time learning to read and write; and with his wife's property established a ship-yard on the Sheepscot river in Maine, but soon abandoned it because of Indian disorders. In 1684–1686, with a commission from the British Crown, he searched vainly for a wrecked Spanish treasure ship of which he had heard while on a voyage to the Bahamas; he found this vessel in 1687, and from it recovered £300,000. Of this amount much went to the duke of Albemarle, who had fitted out the second expedition. Phips received £16,000 as his share, was knighted by James II., and was appointed sheriff of New England under Sir Edmund Andros. Poorly educated and ignorant of law, Phips could accomplish little, and returned to England. In 1689 he returned to Massachusetts, found a revolutionary government in control, and at once entered into the life of the colony. He joined the North Church (Cotton Mather's) at Boston, and was soon appointed by the general court commander of an expedition against the French in Canada, which sailed in April 1690 and easily captured Port Royal. A much larger expedition led by Phips in July against Quebec and Montreal ended disastrously. Phips generously bought at their par value, in order to give them credit in the colony, many of the colony's bills issued to pay for the expedition. In the winter of 1690 he returned to England, vainly sought aid for another expedition against Canada, and urged, with Increase Mather, the colonial agent, a restoration of the colony's charter, annulled during the reign of Charles II. The Crown, at the suggestion of Mather, appointed him the first royal governor under the new charter. On reaching Boston in May 1692, Phips found the colony in a very disordered condition, and though honest, persevering and indisposed to exalt his prerogative at the expense of the people, he was unfitted for the difficult position. He appointed a special commission to try the witchcraft cases, but did nothing to stop the witchcraft mania, and suspended the sittings of the court only after great atrocities had been committed. In defending the frontier he displayed great energy, but his policy of building forts was expensive and therefore unpopular. Having the manners of a 17th-century sea captain, he became involved in many quarrels, and engaged in a bitter controversy with Governor Benjamin Fletcher of New York. Numerous complaints to the home government resulted in his being summoned to England to answer charges. While in London awaiting trial, he died on the 18th of February 1695.

See Cotton Mather's *Life of His Excellency Sir William Phips* (London, 1697; republished in his *Magnalia* in 1702); Francis Bowen's "Life of Sir William Phips," in Jared Sparks's *American Biography*, 1st series, vol. vii. (New York, 1836); William Goold's "Sir William Phips," in *Collections of the Maine Historical Society*, series 1, vol. ix. (Portland, 1887); Ernest Myrand's *Sir William Phips devant Quebec* (Quebec, 1893); Thomas Hutchinson's *History of Massachusetts* (2 vols., Boston; 3rd ed. 1795); and J. G. Palfrey's *History of New England* (5 vols., Boston, 1858–1890).

PHLEBITIS (from Gr. φλέψ, a vein), inflammation of a vein. When a vein is inflamed the blood in it is apt to form a clot, or thrombus, which, if loosened and displaced from its original position, may be carried as an embolus towards the heart and there be arrested; or it may pass through the cavities of the heart into the lungs, there to lodge and to give rise to alarming symptoms. If the thrombus is formed in the inflamed vein of a pile it may pass as an embolus (see Haemorrhoids) into the liver. If an embolus is carried through the left side of the heart it may enter the large vessels at the root of the neck and reach the brain, giving rise to serious cerebral disturbance or

[1] *Chronicle* of Joshua Stylites, ch. 30.

[2] On these and other points see Budge's introduction to his second volume, which contains also a list of the other works of Philoxenus and a number of illustrative extracts.

[3] One by Martin (in *Grammatica chrestomathia et glossarium linguae syriacae*) and one by Guidi (*La Lettera di Filosseno ai monaci di Tell 'Addâ*).

to a fatal paralysis. The thrombus may be formed in gout and rheumatism, or in consequence of stagnation of the blood-current, due to slowing of the circulation in various wasting diseases. When a thrombus forms, absolute rest in the recumbent posture is to be strictly enjoined; the great danger is the displacement of the clot. An inflamed and clotted vein, if near the surface, causes an elongated, dusky elevation beneath the skin, where the vein may be felt as a hard cord, the size, perhaps, of a cedar pencil, or a pen-holder. Its course is marked by great tenderness, and the tissue which was drained by the branches of that vein are livid from congestion, and perhaps boggy and pitting from oedema. If, as often happens, the inflamed vein is one of those running conspicuously upwards from the foot—a saphenous vein (σαφής, distinct)—the patient should be placed in bed with the limb secured on a splint in order to protect it from any rough movement. Should the clot become detached, it might give rise to sudden and alarming faintness possibly even to a fatal syncope. Thus, there is always grave risk with an inflamed and clotted vein, and modern surgery shows that the safest course is, when practicable, to place a ligature on the vein upon the heart-side of the clotted piece and to remove the latter by dissection. When, as sometimes happens, the clot is invaded by septic organisms it is particularly liable to become disintegrated, and if parts of it are carried to various regions of the body they may there give rise to the formation of secondary abscesses. In the ordinary treatment of phlebitis, in addition to the insistence on perfect rest and quiet, fomentations may be applied locally, the limb being kept raised. Massage must not be employed so long as there is any risk of a clot being detached. (E. O.*)

PHLEGON, of Tralles in Asia Minor, Greek writer and freedman of the emperor Hadrian, flourished in the 2nd century A.D. His chief work was the *Olympiads*, an historical compendium in sixteen books, from the 1st down to the 229th Olympiad (776 B.C. to A.D. 137), of which several chapters are preserved in Photius and Syncellus. Two small works by him are extant: *On Marvels*, containing some ridiculous stories about ghosts, prophecies and monstrous births, but instructive as regards ancient superstitions; *On Long-lived Persons*, a list of Italians who had passed the age of 100, taken from the Roman censuses. Other works ascribed to Phlegon by Suidas are a description of Sicily, a work on the Roman festivals in three books, and a topography of Rome.

Fragments in C. Müller, *Frag. hist. graec.* iii.; of the *Marvels* and *Long-lived* in O. Keller, *Rerum naturalium scriptores*, i. (1877); see also H. Diels, "Phlegons Androgynenorakel" in *Sibyllinische Blätter* (1890).

PHLOGOPITE, a mineral belonging to the group of micas (*q.v.*). It is a magnesium mica, differing from biotite in containing only a little iron; the chemical formula is $[H,K,(MgF)]_3Mg_3Al(SiO_4)_3$. It crystallizes in the monoclinic system, but the crystals are roughly developed. There is a perfect cleavage parallel to the basal plane; the cleavage flakes are not quite so elastic as those of muscovite. Sometimes it is quite colourless and transparent, but usually of a characteristic yellowish-brown colour, and often with a silvery lustre on the cleavage surfaces, hence the trade name "silver amber mica" for some varieties. The name phlogopite is from Gr. φλογωπός (fiery-looking), the mineral being sometimes brownish-red and coppery in appearance. The hardness is 2½–3, and the specific gravity 2·78–2·85. The optic axial plane is parallel to the plane of symmetry and the axial angle 0°–10°. Phlogopite occurs chiefly as scales and plates embedded in crystalline limestones of the Archean formation. The mica mined in Canada and Ceylon is mainly phlogopite, and is largely used as an insulator for electrical purposes. In Canada it occurs with apatite in pyroxene rocks which are intrusive in Laurentian gneisses and crystalline limestones, the principal mining district being in Ottawa county in Quebec and near Burgess in Lanark county, Ontario. In Ceylon, the mineral forms irregular veins, rarely exceeding one or two feet in width, traversing granulite, especially near the contact of this rock with crystalline limestone. (L. J. S.)

PHLOX (Nat. Ord. *Polemoniaceae*), a genus of about 30 species, mostly perennial hardy plants of great beauty, natives of North America (one occurs in Siberia), with entire, usually opposite, leaves and showy flowers generally in terminal clusters. Each flower has a tubular calyx with five lobes, and a salver-shaped corolla with a long slender tube and a flat limb. The five stamens are given off from the tube of the corolla at different heights and do not protrude beyond it. The ovary is three-celled with one to two ovules in each cell; it ripens into a three-valved capsule. Many of the species and varieties are tall herbs yielding a wealth of bloom throughout the summer and early autumn. These require a deep, rich, and rather heavy loam, and a cool, moist position to flourish.

The dwarf perennial species and varieties, the "moss pinks" of gardens, are charming plants for the rockery and as edging to beds and borders. They are trailing and tufted in habit, the branches rooting at the nodes. They succeed in poorer soil, and drier situations than the tall kinds. Seed is seldom produced. Propagation is effected by cuttings in July and early August, placed in a cold frame, and by division of the plants, which should be lifted carefully, and cut into rooted portions as required. The tufted kinds decay in patches in winter if the situation is moist and the weather mild and wet.

Phlox Drummondii and its numerous varieties are half-hardy annuals in Britain. It is a small-growing hairy plant, flowering profusely during the summer months. For early flowering it should be sown in heat in March and April and transferred out of doors in June. It succeeds if sown out of doors in April, but the flowering season is later and shorter.

The tall-growing border phloxes are divided into early and late flowering kinds respectively, the former derived mainly from *P. glaberrima* and *P. suffruticosa*, and the latter from *P. maculata* and *P. paniculata*. The salver-shaped flowers with cylindrical tubes range from pure white to almost bright scarlet in colour, passing through shades of pink, purple, magenta lilac, mauve and salmon. New varieties are obtained by the selection of seedlings. Owing to the frequent introduction of new kinds, the reader is referred to the current lists published by growers and nurserymen. The "moss pinks," *P. subulata* and its varieties, are all worthy of a place in the alpine garden.

The varieties are relatively few. The following list includes nearly all the best kinds:—

P. subulata, pink with dark centre; *Aldboroughensis*, rose; *annulata*, bluish white, ringed with purple; *atrolilacina*, deep lilac; *atropurpurea* purple-rose and crimson; Brightness, bright rose with scarlet eye; *compacta*, clear rose; Fairy, lilac; G. F. Wilson, mauve; *grandiflora*, pink, crimson blotch; Little Dot, white, blue centre; *Nelsoni*, pure white; Vivid, rose, carmine centre; all these are about 4 in. high. *P. divaricata*, lavender, height 1 ft.; *P. ovata*, rose, 1 ft.; *P. reptans*, rose, 6 in.; and *P. amoena*, rose, 9 in., are also charming alpines.

P. Drummondii varieties come true from seed, but are usually sown in mixture.

PHOCAEA (mod. *Fokia* or *Fokha*), an ancient city on the western coast of Asia Minor, famous as the mother city of Marseilles. It was the most northern of the Ionian cities, and was situated on the coast of the peninsula which separates the gulf of Cyme, occupied by Aeolian settlers, from the Hermaean Gulf, on which stood Smyrna and Clazomenae.[1] Its position between two good harbours, Naustathmus and Lampter (Livy xxxvii. 31), led the inhabitants to devote themselves to maritime pursuits. According to Herodotus the Phocaeans were the first of all the Greeks to undertake distant voyages, and made known the coasts of the Adriatic, Tyrrhenia and Spain. Arganthonius, king of Tartessus in Spain, invited them to emigrate in a body to his dominions, and, on their declining, presented them with a large sum of money. This they employed in constructing a strong wall around their city, a defence which stood them in good stead when Ionia was attacked by Cyrus in 546. Eventually they determined to seek a new home in the west, where they already had flourishing colonies, *e.g.*

[1] It was said to have been founded by a band of emigrants from Phocis, under the guidance of two Athenian leaders, named Philogenes and Damon, but it joined the Ionian confederacy by accepting the government of Athenian rulers of the house of Codrus.

Alalia in Corsica and Massilia (mod. Marseilles). A large part of the emigrants proceeded only as far as Chios, returned to Phocaea, and submitted to the Persian yoke.

Phocaea continued to exist under the Persian government, but greatly reduced in population and commerce. Though it joined in the Ionian revolt against Persia in 500 it was able to send only three ships to the combined fleet which fought at Lade. But a Phocaean took the supreme command. It never again played a prominent part in Ionian history, and is rarely mentioned. In the time of Timur Fujah was a fortress of Sarukhan, but had been previously in Genoese hands. The ruins still visible on the site bear the name of Palaea Fokia, but they are of little interest. The modern town in the immediate neighbourhood, still known as Fokia, was founded by the Genoese in 1421 on account of the rich alum mines in the neighbourhood. It has a fair natural harbour, which is the nearest outlet of the rich district of Menemen. About 1880, while the Gediz Chai was throwing its silt unchecked into the Gulf of Smyrna and gradually filling the navigable channel, there was talk of reviving Fokia as a new port for Smyrna, and connecting it with the Cassaba railway. But, in deference to Smyrniote protests, a new estuary was cut for the Gediz. Fokia has acquired local importance however as a port of call for coasting steamers, and it is used to some degree as a summer residence by Smyrniotes.

(D. G. H.)

PHOCAS, East Roman emperor (602–610), was a Cappadocian of humble origin. He was still but a centurion when chosen by the army of the Danube to lead it against Constantinople. A revolt within the city soon afterwards resulted in the abdication of the reigning emperor Maurice, and in the elevation of Phocas to the throne, which seems to have been accomplished by one of the circus factions against the wish of the troops. Phocas proved entirely incapable of governing the empire. He consented to pay an increased tribute to the Avars and allowed the Persians, who had declared war in 604 under Chosroes II., to overrun the Asiatic provinces and to penetrate to the Bosporus. When the African governor Heraclius declared against him, Phocas was deserted by the starving populace of Constantinople, and deposed with scarcely a struggle (610). He died in the same year on the scaffold.

See J. B. Bury, *The Later Roman Empire* (London, 1889), ii. 197–206.

PHOCION, Athenian statesman and general, was born about 402 B.C.,[1] the son of a small manufacturer. He became a pupil of Plato and in later life was a close friend of Xenocrates. This academic training left its mark upon him, but it was as a soldier rather than as a philosopher that he first came into notice. Under Chabrias he distinguished himself in the great sea-fight of Naxos (376), and in the subsequent campaigns loyally supported his chief. He won the confidence of the allies by his justice and integrity. In 351–349[2] he entered the Persian service and helped to subdue a rebellion in Cyprus. Henceforward he always held a prominent position in Athens, and although he never canvassed he was elected general forty-five times in all. In politics he is known chiefly as the consistent opponent of the anti-Macedonian firebrands, headed by Demosthenes, Lycurgus and Hyperides, whose fervent eloquence he endeavoured to damp by recounting the plain facts of Athens's military and financial weakness and her need of peace, even when the arms of Athens seemed to prosper most. But although he won the respect of his audience, his advice was frequently discarded. Yet his influence was felt at the trial of Aeschines in 343, whom he helped to defend, and after the disaster of Chaeronea (338), when he secured very lenient terms from Philip. He also rendered good service in the field; in 348 he saved the force operating against the philo-Macedonian tyrants in Euboea by the brilliant victory of Tamynae. Under the Macedonian predominance his reputation steadily increased. Though by no means inclined to truckle to the Macedonians, as is shown by his protection of the refugee Harpalus and his spirited campaign in defence of Attica in 322, he won the confidence of the conquerors, and in the restricted democracy which Antipater enforced he became the virtual ruler of Athens. Old age, however, was telling on him; when Polyperchon by his proclamation of "freedom" raised a new crisis in 318, Phocion's dilatoriness was interpreted as active treason on Cassander's behalf, and the people, incited by the restored democrats, deposed him from office. Phocion fled to Polyperchon, but was sent back by the latter to be tried at Athens. The assembly, containing numerous slaves and all the city mob, shouted Phocion down and condemned him to death unheard. Not long after, the Athenians decreed a public burial and a statue in his honour.

Phocion's character and policy were throughout inspired by his philosophic training, which best explains his remarkable purity of character and his prudent councils. To the same influence we may ascribe his reserve and his reluctance to co-operate heartily either with the people or with the Macedonian conquerors who put their trust in him: a greater spirit of energy and enterprise might have made him the saviour of his country. Phocion remained famous in antiquity for the pithy sayings with which he used to parry the eloquence of his opponents. Demosthenes called him "the chopper of my periods."

Plutarch (*Life of Phocion*) draws much good information from Philochorus and Duris (who reproduces Hieronymus of Cardia); his numerous anecdotes are repeated in other works of his and in Aelian (*Var. hist.*). Diodorus (xvi.–xviii.) is likewise based on Duris. See Holm, *Gk. Hist.* vol. iii. (Eng. trans., London, 1896).

(M. O. B. C.)

[1] Diodorus' statement that Phocion was 75 at his death (i.e. that he became general at 30 and was elected 45 years in succession) [illegible] as the date of birth; but he must have been over 25 as second-in-command at Naxos (376).

[2] The chronology is uncertain; the dates given for this period are Beloch's (*Griechische Geschichte*, ii.).

PHOCIS, an ancient district of central Greece (now a department, pop. 62,246), about 625 sq. m. in area, bounded on the W. by Ozolian Locris and Doris, on the N. by Opuntian Locris, on the E. by Boeotia, and on the S. by the Corinthian Gulf. The massive ridge of Parnassus (8068 ft.), which traverses the heart of the country, divides it into two distinct portions. Between this central barrier and the northern frontier range of Cnemis (3000 ft.) is the narrow but fertile valley of the Cephissus, along which most of the Phocian townships were scattered. Under the southern slope of Parnassus were situated the two small plains of Crisa and Anticyra, separated by Mt Cirphis, an offshoot from the main range. Being neither rich in material resources nor well placed for commercial enterprise, Phocis was mainly pastoral. No large cities grew up within its territory, and its chief places were mainly of strategic importance.

The early history of Phocis remains quite obscure. From the scanty notices of Greek legend it may be gathered that an influx of tribes from the north contributed largely to its population, which was reckoned as Aeolic. It is probable that the country was originally of greater extent, for there was a tradition that the Phocians once owned a strip of land round Daphnus on the sea opposite Euboea, and carried their frontier to Thermopylae; in addition, in early days they controlled the great sanctuary of Delphi. The restriction of their territory was due to the hostility of their neighbours of Boeotia and Thessaly, the latter of whom in the 6th century even carried their raids into the Cephissus valley. Moreover, the Dorian population of Delphi constantly strove to establish its independence and about 590 B.C. induced a coalition of Greek states to proclaim a "Sacred War," and free the oracle from Phocian supervision. Thus their influence at Delphi was restricted to the possession of two votes in the Amphictyonic Council.

During the Persian invasion of 480 the Phocians at first joined in the national defence, but by their irresolute conduct at Thermopylae lost that position for the Greeks; in the campaign of Plataea they were enrolled on the Persian side. In 457 an attempt to extend their influence to the head-waters of the Cephissus in the territory of Doris brought a Spartan army into Phocis in defence of the "metropolis of the Dorians." A similar enterprise against Delphi in 448 was again frustrated by Sparta, but not long afterwards the Phocians recaptured the sanctuary with the help of the Athenians, with whom they

had entered into alliance in 454. The subsequent decline of Athenian land-power had the effect of weakening this new connexion; at the time of the Peloponnesian War Phocis was nominally an ally and dependent of Sparta, and had lost control of Delphi.

In the 4th century Phocis was constantly endangered by its Boeotian neighbours. After helping the Spartans to invade Boeotia during the Corinthian War (395–94), the Phocians were placed on the defensive. They received assistance from Sparta in 380, but were afterwards compelled to submit to the growing power of Thebes. The Phocian levy took part in Epaminondas' inroads into Peloponnesus, except in the final campaign of Mantinea (370–62), from which their contingent was withheld. In return for this negligence the Thebans fastened a religious quarrel upon their neighbours, and secured a penal decree against them from the Amphictyonic synod (356). The Phocians, led by two capable generals, Philomelus and Onomarchus, replied by seizing Delphi and using its riches to hire a mercenary army. With the help of these troops the Phocian League at first carried the war into Boeotia and Thessaly, and though driven out of the latter country by Philip of Macedon, maintained itself for ten years, until the exhaustion of the temple treasures and the treachery of its leaders placed it at Philip's mercy. The conditions which he imposed—the obligation to restore the temple funds, and the dispersion of the population into open villages—were soon disregarded. In 339 the Phocians began to rebuild their cities; in the following year they fought against Philip at Chaeronea. Again in 323 they took part in the Lamian War against Antipater, and in 279 helped to defend Thermopylae against the Gauls.

Henceforth little more is heard of Phocis. During the 3rd century it passed into the power of Macedonia and of the Aetolian League, to which in 196 it was definitely annexed. Under the dominion of the Roman republic its national league was dissolved, but was revived by Augustus, who also restored to Phocis the votes in the Delphic Amphictyony which it had lost in 346 and enrolled it in the new Achaean synod. The Phocian League is last heard of under Trajan.

See Strabo, pp. 401, 418, 424–425; Pausanias x. 1–4; E. Freeman, *History of Federal Government* (ed. 1893, London), pp. 113–114; G. Kazarow, *De foederis Phocensium institutis* (Leipzig, 1899); B. Head, *Historia numorum* (Oxford, 1887), pp. 287–288. (M. O. B. C.)

PHOCYLIDES, Greek gnomic poet of Miletus, contemporary of Theognis, was born about 560 B.C. A few fragments of his "maxims" have been preserved (chiefly in the *Florilegium* of Stobaeus), in which he expresses his contempt for the pomps and vanities of rank and wealth, and sets forth in simple language his ideas of honour, justice and wisdom. A complete didactic poem (230 hexameters) called Ποίημα νουθετικόν or γνῶμαι, bearing the name of Phocylides, is now considered to be the work of an Alexandrian Christian of Jewish origin who lived between 170 B.C. and A.D. 50. The Jewish element is shown in verbal agreement with passages of the Old Testament (especially the book of Sirach); the Christian by the doctrine of the immortality of the soul and the resurrection of the body. Some Jewish authorities, however, maintain that there are in reality no traces of Christian doctrine to be found in the poem, and that the author was a Jew. The poem was first printed at Venice in 1495, and was a favourite school textbook during the Reformation period.

See fragments and the spurious poem in T. Bergk, *Poetae lyrici graeci*, ii. (4th ed., 1882); J. Bernays, *Über das Phokylideische Gedicht* (1858); *Phocylides, Poem of Admonition*, with introduction and commentaries by J. B. Feuling, and translation by H. D. Goodwin (Andover, Mass., 1879); F. Susemihl, *Geschichte der griechischen Litteratur in der Alexandrinerzeit* (1892), ii. 642; S. Krauss (*s.v.* "Pseudo-Phocylides") in *The Jewish Encyclopedia*, and E. Schürer, *Hist. of the Jewish People*, div. ii., vol. iii. 313–316 (Eng. trans., 1886), where full bibliographies are given. There is an English verse translation by W. Hewett (Watford, 1840), *The Perceptive Poem of Phocylides.*

PHOEBE, in astronomy, the ninth satellite of Saturn in order of discovery, or the tenth and outermost now known in the order of distance. It was discovered by W. H. Pickering in 1899 by photographs of the stars surrounding Saturn. It is remarkable in that its motion around the planet is retrograde. (See SATURN.)

PHOEBUS (Gr. for "bright," "pure,"), a common epithet of Apollo (*q.v.*). Artemis in like manner is called Phoebe, and in the Latin poets and their modern followers Phoebus and Phoebe are often used simply for the sun and moon respectively.

PHOENICIA, in ancient geography, the name given to that part of the seaboard of Syria which extends from the Eleutherus (Nahr el-Kebīr) in the north to Mt Carmel in the south, a distance of rather more than two degrees of latitude. These limits, however, were exceeded at various times; thus, north of the Eleutherus lay Aradus and Marathus, and south of Carmel the border sometimes included Dor and even Joppa. Formed partly by alluvium carried down by perennial streams from the mountains of Lebanon and Galilee, and fringed by great sand-dunes which the sea throws up, Phoenicia is covered with a rich and fertile soil. It is only at the mouth of the Eleutherus and at Acre ('Akkā) that the strip of coast-land widens out into plains of any size; there is a certain amount of open country behind Beirūt; but for the most part the mountains, pierced by deep river-valleys, approach to within a few miles of the coast, or even right down to the sea, as at Rās en-Nākūra (Scala Tyriorum, Jos. *Bell. jud.* ii. 10, 2) and Ras el-Abiaḍ (Pliny's Promunturium Album), where a passage had to be cut in the rock for the caravan road which from time immemorial traversed this narrow belt of lowland. From the flanks of Lebanon, especially from the heights which lie to the north of the Qāsimīyeh or Ḳasimiya (Līṭāny) River, the traveller looks down upon some of the finest landscape in the world; in general features the scenery is not unlike that of the Italian Riviera, but surpasses it in grandeur and a peculiar depth of colouring.

With regard to natural products the country has few worth mentioning; minerals are found in the Lebanon, but not in any quantity; traces of amber-digging have been discovered on the coast; and the purple shell (*murex trunculus* and *brandaris*) is still plentiful. The harbours which played so important a part in antiquity are nearly all silted up, and, with the exception of Beirūt, afford no safe anchorage for the large vessels of modern times. A few bays, facing towards the north, break the coast-line, and small rocky islands are dotted here and there just off the shore. Sidon, Tyre and Aradus, though now connected with the mainland, were built originally upon islands; the Phoenicians preferred such sites, because they were convenient for shipping and easily defended against attack.

The chief towns of ancient Phoenicia, as we know of them from the Amarna tablets (15th century B.C.) and from Egyptian, Assyrian and the Old Testament documents, were the following: Acco (now Acre or 'Akkā, Judg. i. 31), Achzib (now ez-Zīb, ibid.), Ahlab (in Assyrian Mahalliba, ibid.)—three towns on the coast south of Tyre, Ḳānāh (Josh. xix. 28), Tyre (Phoen. Ṣōr, now Ṣūr), Zarephath or Sarepta (1 Kings xvii. 9, now Sarafand), Sidon (now Ṣaidā), Berytus (Biruta in Egyptian, Biruna in the Amarna tablets, now Beirūt), Byblus (in Phoen. and Hebr. Gebal, now Jebeil), Arka, 80 m. north of Sidon (Gen. x. 17, now 'Arḳā), Sin (Assyr. Siannu, ibid.) Simyra (Gen. x. 18, now Ṣumrā), Marathus (now Amrit) not important till the Macedonian period, Arvad or Aradus (in Phoen. Arwād, now Ruād, Gen. x. 18; Ezek. xxvii. 8, 11), the most northerly of the great Phoenician towns, and always famous as a maritime state.

Race and Language.—The Phoenicians were an early offshoot from the Semitic stock, and belonged to the Canaanite branch of it. Curiously enough in Gen. x. Sidon, the "first-born" of Canaan, is classed among the descendants of Ham; but the table of nations in Gen. x. is not arranged upon strict ethnographic principles; perhaps religious antagonism induced the Hebrews to assign to the Canaanites an ancestry different from their own; at any rate the close connexion which existed from an early date between the Phoenicians and the Egyptians may have suggested the idea that both peoples belonged to the same race. The Phoenicians themselves retained some memory of having migrated from older seats on an eastern sea; Herodotus (i. 1; vii. 89) calls it the "red sea," meaning probably the Persian Gulf; the tradition, therefore, seems to show that the

Phoenicians believed that their ancestors came originally from Babylonia. By settling along the Syrian coast they developed a strangely un-Semitic love for the sea, and advanced on different lines from the other Canaanites who occupied the interior. They called themselves Canaanites and their land Canaan; such is their name in the Amarna tablets, *Kinaḫḫi* and *Kinaḫni*; and with this agrees the statement assigned to Hecataeus (*Fr. hist. gr.* i. 17) that Phoenicia was formerly called Χνᾶ, a name which Philo of Byblus adopts into his mythology by making "Chna who was afterwards called Phoinix" the eponym of the Phoenicians (*Fr. hist. gr.* iii. 569). In the reign of Antiochus IV. and his successors the coins of Laodicea of Libanus bear the legend "Of Laodicea which is in Canaan";[1] the Old Testament also sometimes denotes Phoenicia and Phoenicians by "Canaan" and "Canaanites" (Isa. xxiii. 11; Obad. 20; Zeph. i. 11), though the latter names generally have a more extended sense. But "Sidonians" is the usual designation both in the Old Testament and in the Assyrian monuments (*Sidunnu*); and even at the time of Tyre's greatest ascendancy we read of Sidonians and not Tyrians in the Old Testament and in Homer; thus Ethbaal king of Tyre (Jos. *Ant.* viii. 13, 2) is called king of the Sidonians in 1 Kings xvi. 31. In the Homeric poems we meet with Σιδόνιοι, Σιδονίη (*Od.* iv. 618; *Il.* vi. 290; *Od.* xiii. 285; *Il.* vi. 291) and Φοίνικες, Φοινίκη (*Od.* xiii. 272, xiv. 288 seq., &c.), and both terms together (*Od.* iv. 83 seq., *Il.* xxiii. 743 seq.).[2] And the Phoenicians themselves used Sidonians as a general name; thus in the oldest Phoenician inscription known (*CIS.* i. 5 = *NSI.*, No. 11), Hiram II. king of Tyre in the 8th century is styled "king of the Sidonians." But among the Greeks "Phoenicians" was the name most in use, Φοίνικες (plur. of Φοῖνιξ) for the people and Φοινίκη for the land (cf. PHOENIX). The former was probably the older word, and may be traced to φοινός = "blood-red"; the Canaanite sailors were spoken of as the "red men" on account of their sunburnt skin; then the land from which they came was called after them; and then probably the original connexion between Φοῖνιξ and φοινός was forgotten, and new forms and meanings were invented. Thus φοῖνιξ came to mean a "date-palm"; but the date-palm is not in the least characteristic of Phoenicia, and can hardly grow there; φοῖνιξ in this sense has no connexion with the original meaning of Phoenician. A derivation has been sought elsewhere, and the Egyptian *Fenḫ* proposed as the origin of the name; but the word *Fenḫ* was apparently used of Asiatic barbarians in general, without any special reference to the Phoenicians (W. M. Müller, *Asien u. Europa*, p. 208 seq.). The Lat. *Poenus* is of course merely an adaptation of the Greek form.[3]

Language.—Inscriptions, coins, topographical names preserved by Greek and Latin writers, names of persons and the Punic passages in the *Poenulus* of Plautus, all show conclusively that the Phoenician language belonged to the North-Semitic group, and to that subdivision of it which is called the Canaanite and includes Hebrew and the dialect of Moab. A comparison between Phoenician and Hebrew reveals close resemblances both in grammatical forms and in vocabulary; in some respects older features have been preserved in Phoenician, others are later, others again are peculiar to the dialect; many words poetic or rare or late in Hebrew are common in Phoenician. Hence we may conclude that the two languages developed independently from a common ancestor, which can be no other than the ancient Canaanite, of which a few words have survived in the Canaanite glosses to the Amarna tablets (written in Babylonian).[4] But in forming an estimate of the Phoenician language it must be remembered that our material is scanty and limited in range; the Phoenicians were in no sense a literary people; moreover, with one exception (*CIS.* i. 5), almost all the inscriptions are subsequent to the 6th century B.C.; the majority belong to the 4th century and later, by which time the language must have undergone a certain amount of decay.[5] Indirectly, however, the Phoenicians rendered one great service to literature; they took a large share in the development and diffusion of the alphabet which forms the foundation of Greek (Herod. v. 58) and of all European writing. The Phoenician letters in their earlier types are practically identical with those used by the Hebrews (*e.g.* the Siloam inscr. *NSI.* No. 2), the Moabites (*e.g.* the Mesha stone, ibid. No. 1), and the Aramaeans of north Syria (*e.g.* the Zenjirli inscrr. ibid. Nos. 61–63). They passed through various modifications in the course of time; after leaving the mother country the script acquires a more cursive, flowing style on the stones from Cyprus and Attica; the tendency becomes more strongly marked at the Punic stage; until in the neo-Punic, from the destruction of Carthage (146 B.C.) to the 1st century A.D., both the writing and the language reached their most degenerate form. As a rustic dialect the language lasted on in North Africa till the 5th century A.D. In his sermons St Augustine frequently quotes Punic words.

Early Period.

History.—The Phoenicians, in imitation of the Egyptians, claimed that their oldest cities had been founded by the gods themselves, and that their race could boast an antiquity of 30,000 years (Africanus in Syncellus, p. 31). Herodotus quotes (ii. 44) a more moderate tradition which placed the foundation of Tyre 2300 years before his time, *i.e.* *c.* 2756 B.C. According to Justin (xviii. 3) the Phoenicians, who had long been settled on the coast and occupied Sidon, founded Tyre in the year before the fall of Troy; possibly the date 1198 B.C., given by Menander of Ephesus (in Jos. *Ant.* viii. 3, 1 and *c. Ap.* i. 18) as that from which the era of Tyre begins, may refer to the epoch which Justin mentions. Little certainty, however, can be allowed to these traditional chronologies. It is probable that in remote ages Babylonia exercised a considerable influence upon Syria and its coast towns; but Mr L. W. King has shown that the tradition, which was supposed to connect Sargon I. (*c.* 3800 B.C.) with the western land and sea, has been misunderstood; it was the sea in the east, *i.e.* the Persian Gulf, which Sargon crossed (*Chronicles concerning Early Bab. Kings*, vol. i. ch. 2, 1907).

Egyptian Rule c. 1600–1100 B.C.

The extension of the Egyptian empire in the direction of Asia began about 1600 B.C. under Aḥmosi (Aahmes, Amasis) I., the founder of the XVIIIth Dynasty, who carried his arms into Syria, and conquered at least Palestine and Phoenicia, the latter being the country called *Da-hi* on the Egyptian monuments (Müller, *As. u. Eur.* p. 181). Whether the campaign of Thothmes (Tethmosis) I. to the Euphrates produced any lasting results is doubtful; it was Thothmes III. (1503–1449) who repeated and consolidated the earlier conquest, and established Egyptian suzerainty over all the petty states of Syria and Phoenicia (see EGYPT: *History*, I.). For the geography and civilization of Canaan about 1400 B.C. we have valuable evidence in the Egyptian papyrus Anastasi I., which mentions Kepuna (Gubna, Gebal-Byblus) the holy city, and continues: "Come then to Berytus, to Sidon, to Sarepta. Where is the ford of Nat-'ana (? Nahr el-Ḳāsimīyeh, or a town)? Where is 'Eutu (? Usu, Palaetyrus)? Another city on the sea is called a haven, D'ar (Tyre) is its name, water is carried to it in boats; it is richer in fish than in sands."[6] But the fullest information about the state of Phoenicia in the 15th and 14th centuries B.C. comes from the Amarna tablets, among which are many letters from the subject princes and the Egyptian governors of Phoenicia to the Pharaoh.[7] It was a time of much political disturbance. The Hittites (*q.v.*) were invading Syria; nomads from the desert supported the invasion; and many of the local chiefs were ready to seize the opportunity to throw off the yoke of Egypt. The towns of Phoenicia were

[1] Cooke, *North-Semitic Inscriptions* (elsewhere abbreviated *NSI.*), No. 149 B. 8.

[2] In this passage "Phoenicians" is a general name for carriers of commerce, not the inhabitants of a particular country. Similarly "Sidonian" in *Il.* vi. 209, is taken to mean Semites in general. Elsewhere "Phoenicians" are merchants, kidnappers, &c., "Sidonians" are artists; to indicate nationality both names seem to be used indifferently, *e.g.* *Od.* xiii. 272, xiv. 288, xv. 414.

had entered into alliance in 454. The subsequent decline of Athenian land-power had the effect of weakening this new connexion; at the time of the Peloponnesian War Phocis was nominally an ally and dependent of Sparta, and had lost control of Delphi.

In the 4th century Phocis was constantly endangered by its Boeotian neighbours. After helping the Spartans to invade Boeotia during the Corinthian War (395–94), the Phocians were placed on the defensive. They received assistance from Sparta in 380, but were afterwards compelled to submit to the growing power of Thebes. The Phocian levy took part in Epaminondas' inroads into Peloponnesus, except in the final campaign of Mantinea (370–62), from which their contingent was withheld. In return for this negligence the Thebans fastened a religious quarrel upon their neighbours, and secured a penal decree against them from the Amphictyonic synod (356). The Phocians, led by two capable generals, Philomelus and Onomarchus, replied by seizing Delphi and using its riches to hire a mercenary army. With the help of these troops the Phocian League at first carried the war into Boeotia and Thessaly, and though driven out of the latter country by Philip of Macedon, maintained itself for ten years, until the exhaustion of the temple treasures and the treachery of its leaders placed it at Philip's mercy. The conditions which he imposed—the obligation to restore the temple funds, and the dispersion of the population into open villages—were soon disregarded. In 339 the Phocians began to rebuild their cities; in the following year they fought against Philip at Chaeronea. Again in 323 they took part in the Lamian War against Antipater, and in 279 helped to defend Thermopylae against the Gauls.

Henceforth little more is heard of Phocis. During the 3rd century it passed into the power of Macedonia and of the Aetolian League, to which in 196 it was definitely annexed. Under the dominion of the Roman republic its national league was dissolved, but was revived by Augustus, who also restored to Phocis the votes in the Delphic Amphictyony which it had lost in 346 and enrolled it in the new Achaean synod. The Phocian League is last heard of under Trajan.

PHOCYLIDES, Greek gnomic poet of Miletus, contemporary of Theognis, was born about 560 B.C. A few fragments of his "maxims" have been preserved (chiefly in the *Florilegium* of Stobaeus), in which he expresses his contempt for the pomps and vanities of rank and wealth, and sets forth in simple language his ideas of honour, justice and wisdom. A complete didactic poem (230 hexameters) called Ποίημα νουθετικόν or γνῶμαι, bearing the name of Phocylides, is now considered to be the work of an Alexandrian Christian of Jewish origin who lived between 170 B.C. and A.D. 50. The Jewish element is shown in verbal agreement with passages of the Old Testament (especially the book of Sirach); the Christian by the doctrine of the immortality of the soul and the resurrection of the body. Some Jewish authorities, however, maintain that there are in reality no traces of Christian doctrine to be found in the poem, and that the author was a Jew. The poem was first printed at Venice in 1495, and was a favourite school textbook during the Reformation period.

See fragments and the spurious poem in T. Bergk, *Poetae lyrici graeci*, ii. (4th ed., 1882); J. Bernays, *Über das Phokylideische Gedicht* (1858); *Phocylides, Poem of Admonition*, with introduction and commentaries by J. B. Feuling, and translation by H. D. Goodwin (Andover, Mass., 1879); F. Susemihl, *Geschichte der griechischen Litteratur in der Alexandrinerzeit* (1892), ii. 642; S. Krauss (*s.v.* "Pseudo-Phocylides") in *The Jewish Encyclopedia*, and E. Schürer, *Hist. of the Jewish People*, div. ii., vol. iii. 313–316 (Eng. trans., 1886), where full bibliographies are given. There is an English verse translation by W. Hewett (Watford, 1840), *The Perceptive Poem of Phocylides*.

PHOEBE, in astronomy, the ninth satellite of Saturn in order of discovery, or the tenth and outermost now known in the order of distance. It was discovered by W. H. Pickering in 1899 by photographs of the stars surrounding Saturn. It is remarkable in that its motion around the planet is retrograde. (See SATURN.)

PHOEBUS (Gr. for "bright," "pure,"), a common epithet of Apollo (*q.v.*). Artemis in like manner is called Phoebe, and in the Latin poets and their modern followers Phoebus and Phoebe are often used simply for the sun and moon respectively.

PHOENICIA, in ancient geography, the name given to that part of the seaboard of Syria which extends from the Eleutherus (Nahr el-Kebîr) in the north to Mt Carmel in the south, a distance of rather more than two degrees of latitude. These limits, however, were exceeded at various times; thus, north of the Eleutherus lay Aradus and Marathus, and south of Carmel the border sometimes included Dor and even Joppa. Formed partly by alluvium carried down by perennial streams from the mountains of Lebanon and Galilee, and fringed by great sand-dunes which the sea throws up, Phoenicia is covered with a rich and fertile soil. It is only at the mouth of the Eleutherus and at Acre ('Akkā) that the strip of coast-land widens out into plains of any size; there is a certain amount of open country behind Beirūt; but for the most part the mountains, pierced by deep river-valleys, approach to within a few miles of the coast, or even right down to the sea, as at Rās en-Nākūra (Scala Tyriorum, Jos. *Bell. jud.* ii. 10, 2) and Ras el-Abiaḍ (Pliny's Promunturium Album), where a passage had to be cut in the rock for the caravan road which from time immemorial traversed this narrow belt of lowland. From the flanks of Lebanon, especially from the heights which lie to the north of the Qāsimīyeh or Ḳasimiya (Liṭāny) River, the traveller looks down upon some of the finest landscape in the world; in general features the scenery is not unlike that of the Italian Riviera, but surpasses it in grandeur and a peculiar depth of colouring.

With regard to natural products the country has few worth mentioning; minerals are found in the Lebanon, but not in any quantity; traces of amber-digging have been discovered on the coast; and the purple shell (*murex trunculus* and *brandaris*) is still plentiful. The harbours which played so important a part in antiquity are nearly all silted up, and, with the exception of Beirūt, afford no safe anchorage for the large vessels of modern times. A few bays, facing towards the north, break the coast-line, and small rocky islands are dotted here and there just off the shore. Sidon, Tyre and Aradus, though now connected with the mainland, were built originally upon islands; the Phoenicians preferred such sites, because they were convenient for shipping and easily defended against attack.

The chief towns of ancient Phoenicia, as we know of them from the Amarna tablets (15th century B.C.) and from Egyptian, Assyrian and the Old Testament documents, were the following: Acco (now Acre or 'Akkā, Judg. i. 31), Achzib (now ez-Zib, ibid.), Ahlab (in Assyrian Mahalliba, ibid.)—three towns on the coast south of Tyre, Ḳānāh (Josh. xix. 28), Tyre (Phoen. Ṣōr, now Ṣūr), Zarephath or Sarepta (1 Kings xvii. 9, now Sarafand), Sidon (now Ṣaidā), Berytus (Biruta in Egyptian, Biruna in the Amarna tablets, now Beirūt), Byblus (in Phoen. and Hebr. Gebal, now Jebeil), Arka, 80 m. north of Sidon (Gen. x. 17, now 'Arḳā), Sin (Assyr. Siannu, ibid.) Simyra (Gen. x. 18, now Ṣumrā), Marathus (now Amrit) not important till the Macedonian period, Arvad or Aradus (in Phoen. Arwād, now Ruād, Gen. x. 18; Ezek. xxvii. 8, 11), the most northerly of the great Phoenician towns, and always famous as a maritime state.

Race and Language.—The Phoenicians were an early offshoot from the Semitic stock, and belonged to the Canaanite branch of it. Curiously enough in Gen. x. Sidon, the "first-born" of Canaan, is classed among the descendants of Ham; but the table of nations in Gen. x. is not arranged upon strict ethnographic principles; perhaps religious antagonism induced the Hebrews to assign to the Canaanites an ancestry different from their own; at any rate the close connexion which existed from an early date between the Phoenicians and the Egyptians may have suggested the idea that both peoples belonged to the same race. The Phoenicians themselves retained some memory of having migrated from older seats on an eastern sea; Herodotus (i. 1; vii. 89) calls it the "red sea," meaning probably the Persian Gulf; the tradition, therefore, seems to show that the

Phoenicians believed that their ancestors came originally from Babylonia. By settling along the Syrian coast they developed a strangely un-Semitic love for the sea, and advanced on different lines from the other Canaanites who occupied the interior. They called themselves Canaanites and their land Canaan; such is their name in the Amarna tablets, *Kinaḫḫi* and *Kinaḫni*; and with this agrees the statement assigned to Hecataeus (*Fr. hist. gr.* i. 17) that Phoenicia was formerly called Χνᾶ, a name which Philo of Byblus adopts into his mythology by making "Chna who was afterwards called Phoinix" the eponym of the Phoenicians (*Fr. hist. gr.* iii. 569). In the reign of Antiochus IV. and his successors the coins of Laodicea of Libanus bear the legend "Of Laodicea which is in Canaan";[1] the Old Testament also sometimes denotes Phoenicia and Phoenicians by "Canaan" and "Canaanites" (Isa. xxiii. 11; Obad. 20; Zeph. i. 11), though the latter names generally have a more extended sense. But "Sidonians" is the usual designation both in the Old Testament and in the Assyrian monuments (*Sidunnu*); and even at the time of Tyre's greatest ascendancy we read of Sidonians and not Tyrians in the Old Testament and in Homer; thus Ethbaal king of Tyre (Jos. *Ant.* viii. 13, 2) is called king of the Sidonians in 1 Kings xvi. 31. In the Homeric poems we meet with Σιδόνιοι, Σιδονίη (*Od.* iv. 618; *Il.* vi. 290; *Od.* xiii. 285; *Il.* vi. 291) and Φοίνικες, Φοινίκη (*Od.* xiii. 272, xiv. 288 seq., &c.), and both terms together (*Od.* iv. 83 seq., *Il.* xxiii. 743 seq.).[2] And the Phoenicians themselves used Sidonians as a general name; thus in the oldest Phoenician inscription known (*CIS.* i. 5 = *NSI.*, No. 11), Hiram II. king of Tyre in the 8th century is styled "king of the Sidonians." But among the Greeks "Phoenicians" was the name most in use, Φοίνικες (plur. of Φοῖνιξ) for the people and Φοινίκη for the land (cf. PHOENIX). The former was probably the older word, and may be traced to φοινός = "blood-red"; the Canaanite sailors were spoken of as the "red men" on account of their sunburnt skin; then the land from which they came was called after them; and then probably the original connexion between Φοῖνιξ and φοινός was forgotten, and new forms and meanings were invented. Thus φοῖνιξ came to mean a "date-palm"; but the date-palm is not in the least characteristic of Phoenicia, and can hardly grow there; φοῖνιξ in this sense has no connexion with the original meaning of Phoenician. A derivation has been sought elsewhere, and the Egyptian *Fenḫ* proposed as the origin of the name; but the word *Fenḫ* was apparently used of Asiatic barbarians in general, without any special reference to the Phoenicians (W. M. Müller, *Asien u. Europa*, p. 208 seq.). The Lat. *Poenus* is of course merely an adaptation of the Greek form.[3]

Language.—Inscriptions, coins, topographical names preserved by Greek and Latin writers, names of persons and the Punic passages in the *Poenulus* of Plautus, all show conclusively that the Phoenician language belonged to the North-Semitic group, and to that subdivision of it which is called the Canaanite and includes Hebrew and the dialect of Moab. A comparison between Phoenician and Hebrew reveals close resemblances both in grammatical forms and in vocabulary; in some respects older features have been preserved in Phoenician, others are later, others again are peculiar to the dialect; many words poetic or rare or late in Hebrew are common in Phoenician. Hence we may conclude that the two languages developed independently from a common ancestor, which can be no other than the ancient Canaanite, of which a few words have survived in the Canaanite glosses to the Amarna tablets (written in Babylonian).[4] But in forming an estimate of the Phoenician language it must be remembered that our material is scanty and limited in range; the Phoenicians were in no sense a literary people; moreover, with one exception (*CIS.* i. 5), almost all the inscriptions are subsequent to the 6th century B.C.; the majority belong to the 4th century and later, by which time the language must have undergone a certain amount of decay.[5] Indirectly, however, the Phoenicians rendered one great service to literature; they took a large share in the development and diffusion of the alphabet which forms the foundation of Greek (Herod. v. 58) and of all European writing. The Phoenician letters in their earlier types are practically identical with those used by the Hebrews (*e.g.* the Siloam inscr. *NSI.* No. 2), the Moabites (*e.g.* the Mesha stone, ibid. No. 1), and the Aramaeans of north Syria (*e.g.* the Zenjirli inscrr. ibid. Nos. 61–63). They passed through various modifications in the course of time; after leaving the mother country the script acquires a more cursive, flowing style on the stones from Cyprus and Attica; the tendency becomes more strongly marked at the Punic stage; until in the neo-Punic, from the destruction of Carthage (146 B.C.) to the 1st century A.D., both the writing and the language reached their most degenerate form. As a rustic dialect the language lasted on in North Africa till the 5th century A.D. In his sermons St Augustine frequently quotes Punic words.

Early Period.

History.—The Phoenicians, in imitation of the Egyptians, claimed that their oldest cities had been founded by the gods themselves, and that their race could boast an antiquity of 30,000 years (Africanus in Syncellus, p. 31). Herodotus quotes (ii. 44) a more moderate tradition which placed the foundation of Tyre 2300 years before his time, *i.e.* *c.* 2756 B.C. According to Justin (xviii. 3) the Phoenicians, who had long been settled on the coast and occupied Sidon, founded Tyre in the year before the fall of Troy; possibly the date 1198 B.C., given by Menander of Ephesus (in Jos. *Ant.* viii. 3, 1 and *c. Ap.* i. 18) as that from which the era of Tyre begins, may refer to the epoch which Justin mentions. Little certainty, however, can be allowed to these traditional chronologies. It is probable that in remote ages Babylonia exercised a considerable influence upon Syria and its coast towns; but Mr L. W. King has shown that the tradition, which was supposed to connect Sargon I. (*c.* 3800 B.C.) with the western land and sea, has been misunderstood; it was the sea in the east, *i.e.* the Persian Gulf, which Sargon crossed (*Chronicles concerning Early Bab. Kings*, vol. i. ch. 2, 1907).

Egyptian Rule c. 1600–1100 B.C.

The extension of the Egyptian empire in the direction of Asia began about 1600 B.C. under Aḥmosi (Aahmes, Amasis) I., the founder of the XVIIIth Dynasty, who carried his arms into Syria, and conquered at least Palestine and Phoenicia, the latter being the country called *Da-hi* on the Egyptian monuments (Müller, *As. u. Eur.* p. 181). Whether the campaign of Thothmes (Tethmosis) I. to the Euphrates produced any lasting results is doubtful; it was Thothmes III. (1503–1449) who repeated and consolidated the earlier conquest, and established Egyptian suzerainty over all the petty states of Syria and Phoenicia (see EGYPT: *History*, I.). For the geography and civilization of Canaan about 1400 B.C. we have valuable evidence in the Egyptian papyrus Anastasi I., which mentions Kepuna (Gubna, Gebal-Byblus) the holy city, and continues: "Come then to Berytus, to Sidon, to Sarepta. Where is the ford of Nat-'ana (? Nahr el-Ḳāsimīyeh, or a town)? Where is 'Eutu (? Usu, Palaetyrus)? Another city on the sea is called a haven, D'ar (Tyre) is its name, water is carried to it in boats; it is richer in fish than in sands."[6] But the fullest information about the state of Phoenicia in the 15th and 14th centuries B.C. comes from the Amarna tablets, among which are many letters from the subject princes and the Egyptian governors of Phoenicia to the Pharaoh.[7] It was a time of much political disturbance. The Hittites (*q.v.*) were invading Syria; nomads from the desert supported the invasion; and many of the local chiefs were ready to seize the opportunity to throw off the yoke of Egypt. The towns of Phoenicia were

[2] In this passage "Phoenicians" is a general name for carriers of commerce, not the inhabitants of a particular country. Similarly "Sidonian" in *Il.* vi. 209, is taken to mean Semites in general. Elsewhere "Phoenicians" are merchants, kidnappers, &c., "Sidonians" are artists; to indicate nationality both names seem to be used indifferently, *e.g.* *Od.* xiii. 272, xiv. 288, xv. 414.

the lesser towns being under the command of the great cities. Aradus presided over three subordinate townships (Arrian ii. 13); Berytus, which had no king of its own, probably formed with Byblus a single kingdom; while Tripolis consisted of a federation of three cities separated by a stadium from each other, and provided a meeting-place for the federal council, which was chiefly occupied in dealings with the Persian government (Diod. xvi. 41). But federation on a larger scale was never possible in Phoenicia, for the reason that no sense of political unity existed to bind the different states together. Commercial interests dominated everything else, and while these stimulated a municipal life not without vigour, civil discipline and loyalty were but feebly felt. On occasion the towns could defend their independence with strenuous courage; the higher qualities which make for a progressive national life the Phoenicians did not possess.

The Persian Period, 538-333 B.C.

Phoenicia now became part of the fifth satrapy of the Persian Empire, and entered upon a spell of comparative peace and growing prosperity. Favoured for the sake of their fleet, and having common interests against Greece,[1] the Phoenicians were among the most loyal subjects of the empire. At this period Sidon occupied the position of leading state; in the fleet her king ranked next to Xerxes and before the king of Tyre (Herod. viii. 67); her situation afforded advantages for expansion which Tyre on its small and densely populated island could not rival. The city was distinguished by its cosmopolitan character; the satrap resided there when he came to Phoenicia, and the Persian monarch had his paradise outside the walls. In the first half of the 4th century Straton I. (in Phoen. *'Abd-'ashtart* or *Bod-'ashtart*) was king, *c.* 374-362. He cultivated friendly relations with Athens, indicated in a decree of *proxenia* (Michel, *Rec. d'inscr. gr.* No. 93 = *CIG.* No. 87); his court was famed for its luxury; and the extent to which phil-Hellenic tendencies prevailed at this time in Sidon is shown by the royal sarcophagi, noble specimens of Greek art, which have been excavated in the necropolis of the city. It was in the reign of Straton that Tyre fell into the hands of Evagoras, king of Salamis, who had already supplanted Phoenician with Greek civilization in Cyprus (Isocr. *Evag.* 62, *Paneg.* 161; Diod. xv. 2). Straton made friends with Nicocles, son of Evagoras, and with him came to an untimely end through their implication in the great revolt of the satraps, 362 B.C. (see the story of Straton's death in Jerome, *adv. Jovin.* i. 45). A new revolt of Sidon against the Persians took place under King Tennes owing to the insults offered to the Sidonians at the federal diet in Tripolis. With the aid of Nectanebus of Egypt, who had grievances of his own to avenge, the Sidonians carried the rest of Phoenicia with them and drove the satraps of Syria and Cilicia out of the country. Tennes, however, betrayed his people and opened the city to Artaxerxes III.; the inhabitants to the number of 40,000 are said to have set fire to their houses and perished; Tennes himself was executed after he had served the ends of the great king (346 B.C.; Diod. xvi. 41-45). The last king of Sidon was Straton II. ('Abd-'ashtart, 346-332) before the Persian Empire came to an end.[2]

Towards the close of the 5th century the Phoenician coins begin to supplement our historical sources (see NUMISMATICS). From the time of Darius the Persian monarchs issued a gold coinage, and reserved to themselves the right of doing so; but they allowed their satraps and vassal states to coin silver and copper money at discretion. Hence Aradus, Byblus, Sidon and Tyre issued a coinage of their own, of which many specimens exist: the coins are stamped as a rule with emblem or name of the city, sometimes with the name of the ruler.[3] Thus from the coins of Byblus we learn the names of four kings, 'El-pa'al, 'Az-ba'al (between 360 and 340 B.C.), Adar-melek, 'Ain-el; from the coins of the other cities it is difficult to obtain much information. The native inscriptions, however, now become available, though most of them belong to the period which follows, and only a few have been discovered in Phoenicia itself. One of the earliest of these is the inscription of Byblus (*CIS.* i. 1 = *NSI.* No. 3), dating from the Persian period; it records a dedication made by Yeḥaw-milk, king of Gebal, and mentions the name of the king's grandfather, Uri-milk, but the exact dates of their reign are not given.

The Macedonian Period, 333-69 B.C.

When Alexander the Great entered Phoenicia after the battle of Issus (333 B.C.), the kings were absent with the Persian fleet in the Aegean; but the cities of Aradus, Byblus and Sidon welcomed him readily, the last-named showing special zeal against Persia. The Tyrians also offered submission, but refused to allow the conqueror to enter the city and sacrifice to the Tyrian Heracles. Alexander was determined to make an example of the first who should offer opposition, and at once began the siege. It lasted seven months. With enormous toil the king drove out a mole from the mainland to the island and thus brought up his engines; ships from the other Phoenician towns and from Cyprus lent him their aid, and the town at length was forced in July 332; 8000 Tyrians were slain, 30,000 sold as slaves, and only a few notables, the king Azemilkos, and the festal envoys from Carthage who had taken refuge in the sanctuary of Melkarth, were spared (Diod. xvii. 40-46). It is not unlikely that Zech. ix. 2-4 refers to this famous siege. For the time Tyre lost its political existence, while the foundation of Alexandria presently changed the lines of trade, and dealt a blow even more fatal to the Phoenician cities.

During the wars of Alexander's successors Phoenicia changed hands several times between the Egyptian and the Syrian kings. Thus in 312 Tyre was captured from Antigonus by Ptolemy I., the ally of Seleucus; in 287 it passed into the dominion of Seleucus; in 275 again it was captured by Ptolemy II. Philadelphus, and began to recover itself as an autonomous municipality. From the year 275 "the people of Tyre" reckoned their era (*CIS.* i. 7 = *NSI.* No. 9, cf. 10). The Tyrian coins of the period, stamped with native, Greek and Egyptian symbols, illustrate the traditional relations of the city and the range of her ambitions. A special interest attaches to these silver tetradrachms and didrachms (staters and half-staters), because they were used by the Jews for the payment of the temple tax as "shekels of the sanctuary" (*NSI.* pp. 351, 44).

Among the Phoenician states we know most about Sidon during this period. The kingship was continued for a long time. The story goes that Alexander raised to the throne a member of the royal family, Abdalonymus, who was living in obscure poverty and working as a gardener (Justin xi. 10; Curt. iv. 1; Diod. xvii. 47 wrongly connecting the story with Tyre). In 312 Ptolemy, then master of Phoenicia, appointed his general Philocles king of the Sidonians, and a decree in honour of this king has been found at Athens (Michel, No. 387, cf. 1261); but he cannot have reigned long. For at the end of the 4th and the beginning of the 3rd century we have evidence of a native dynasty in the important inscriptions of Tabnith, Eshmun-'azar and Bod-'ashtart, and in the series of inscriptions (repeating the same text) discovered at Bostan esh-Sêkh near Sidon (*NSI.* Nos. 4, 5, 6 and App. i.)[4] The last-named texts imply that the first king of this dynasty was Eshmun-'azar; his son Tabnith succeeded him; then came Eshmun-'azar II., who died young, then Bod-'ashtart, both of them grandsons of Eshmun-'azar I. With Bod-'ashtart, so far as we know, the dynasty came to an end, say about 250 B.C.; and it is not unlikely that the Sidonians reckoned an era of independence from this event (*NSI.* p. 95 *n.*).

Of the other Phoenician cities something is known of the history of Aradus. Its era began in 259 B.C., when it probably became a republic or free city. While the rest of Phoenicia passed under the

[1] The naval expeditions against Greece in 480-449 and Sparta in 396-387 were mainly fitted out by Phoenicia. See PERSIA: *Ancient History*, for the whole of this section.

[2] Justin xviii. 3 tells a story about Tyre during this period: the city, after being worn out though not defeated in long wars with the Persians, was so enfeebled that it was seized by the slaves, who rose and massacred their masters; one Straton alone escaped and was afterwards made king. The reference to the Persians is obviously incorrect; the story, if it can be taken seriously at all, must refer to one of the sieges by the Assyrians or Chaldaeans, and, as Meyer suggests (*Ency. Bib.* col. 3760), may be derived from the story of Abdalonymus of Sidon mentioned below.

[3] See especially E. Babelon, *Les Perses Achéménides*, and cf. *NSI* No. 149.

[4] The date of this dynasty has been much disputed; but the reference to "the lord of kings" in the great inscr. of Eshmun-'azar (line 18) points to the Ptolemaic period, for the Persian monarch is always styled "king of kings." The interpretation of many details of the inscr. from Bostan esh-Shêkh is still uncertain.

rule of Ptolemy II. and his successors between 281 and 197, Aradus remained in the kingdom of the Seleucids, who greatly favoured the city and increased its privileges (Strabo xvi. 2, 14; Polyb. v. 68). But its subject-towns availed themselves of the political changes of the period to throw off their allegiance; Marathus from 278 begins to issue a coinage bearing the heads of the Ptolemies, and later on Karne asserted its independence in the same way; but in the end the Aradians recovered their supremacy. Diodorus records a barbarous attempt made by the Aradians about 148 B.C. to destroy Marathus, which was frustrated by the pity and courage of an Aradian fisherman (xxxiii. 5). At last in the time of Tigranes, the Armenian holder of the kingdom of the Seleucids, or soon afterwards, the coins of Marathus cease; the city was levelled to the ground, and its land, with that of Simyra, was parcelled out among the Aradians (Strabo xvi. 2, 12). Akko issued coins of its own down to 267 B.C., if the reckoning was from the Seleucid era (312 B.C.); in 267 it was converted into a Greek city by Ptolemy, and called Ptolemais (Polyb. iv. 37; Strabo xvi. 2, 25; cf. Acts xxi. 7). Laodicea of Libanus was founded by Seleucus Nicator on the plain south-east of Hemesa (Homs) in the region of the upper Orontes, and became an important city; its coins of the 2nd century B.C. bear the interesting legend in Phoenician, "Of Laodicea which is in Canaan" (*NSI.* p. 349 seq.). Another Laodicea "by the sea" (*ad mare*), also of Seleucid foundation, is probably to be identified with the ruined site called Umm el-'Awāmid, near the coast between Tyre and Akko; several Phoenician inscriptions have been found there (*e.g. CIS.* i. 7 = *NSI.* No. 9; Clermont Ganneau, *Recueil*, t. v.).

After the death of Antiochus IV. Epiphanes in 164 B.C., revolts and adventurers made their appearance in many parts of Syria, heralding the collapse of the kingdom of the Seleucids. Berytus was destroyed by the usurper Trypho in 140 B.C. Tyre in 120 and Sidon in 111 received complete independence, and inaugurated new eras from these dates. Byblus and Tripolis fell into the hands of "tyrants" (Strabo xvi. 2, 18; Jos. *Ant.* xiv. 3, 2), and Arab robbers plundered their territories from strongholds in the Lebanon. From 83–69 B.C. the entire kingdom was held by the Armenian Tigranes.

Roman rule.

At last in 64 B.C. Pompey arrived upon the scene and established order out of chaos. Phoenicia was incorporated into the Roman province of Syria; Aradus, Sidon, Tyre and Tripolis were confirmed in their rights of self-government and in the possession of their territories. In 14 B.C. Augustus rebuilt Berytus as a Roman colony and stationed two legions there; later on Ptolemais, Tyre and Sidon received colonial status. Under the beneficent government of Rome the chief towns prospered and extended their trade; but the whole character of the country underwent a change. During the Macedonian period Greek influences had been steadily gaining ground in Phoenicia; relations with the Greek world grew closer; the native language fell into disuse, and from the beginning of the Roman occupation Greek appears regularly in inscriptions and on coins, though on the latter Phoenician legends do not entirely vanish till the 2nd century A.D.; while the extent to which Hellenic ideas penetrated the native traditions and mythologies is seen in the writings of Philo of Byblus. For the purposes of everyday life, however, the people spoke not Greek, but Aramaic. As elsewhere, the Roman rule tended to obliterate characteristic features of national life, and under it the native language and institutions of Phoenicia became extinct.

Navigation, Trade, Colonies.—The Phoenicians were essentially a seafaring nation. Fearless and patient navigators, they ventured into regions where no one else dared to go, and, always with an eye to their monopoly, they carefully guarded the secrets of their trade routes and discoveries, and their knowledge of winds and currents. At the beginning of the 7th century B.C. a Phoenician fleet is said to have circumnavigated Africa (Herod. iv. 42). To the great powers Phoenician ships and sailors were indispensable; Sennacherib, Psammetichus and Necho, Xerxes, Alexander, all in turn employed them for their transports and sea-fights. Even when Athens had developed a rival navy Greek observers noted with admiration the discipline kept on board the Phoenician ships and the skill with which they were handled (Xen. *Oec.* viii.); all the Phoenician vessels from the round merchant-boat (γαῦλος—after which the island of Gaulus, now Gozo, near Malta was called) to the great Tarshish-ships, the "East-Indiamen" of the ancient world, excelled those of the Greeks in speed and equipment. As E. Meyer points out, the war between the Greeks and the Persians was mainly a contest between the sea-powers of Greece and Phoenicia. At what period did Phoenicia first rise to be a power in the Mediterranean? We are gradually approaching a solution of this obscure problem. Recent discoveries in Crete (*q.v.*) have brought to light the existence of a Cretan or "Minoan" sea-power of remote antiquity, and it is clear that a great deal of what used to be described as Phoenician must receive quite a different designation. The Minoan sea-power was at last broken up by invaders from the north, and a Carian rule became dominant in the Aegean (Herod. i. 171; Thucyd. i. 4, 8). It was a time of disorder and conflict due to the immigration of new races into the ancient seats of civilization, and it synchronized with the weakening of the power of Egypt in the countries which bordered on the eastern Mediterranean. This was in the 12th century B.C. The Tyrian trader saw that his opportunity was come, and the Aegean lay open to his merchant vessels. Where much is still obscure, all that seems certain is that the antiquity of Phoenicia as a sea and trading power has been greatly exaggerated both in ancient and in modern times; the Minoan power of Cnossus preceded it by many centuries; the influence of Phoenicia in the Aegean cannot be carried back much earlier than the 12th century B.C., and, comparatively speaking, it was "foreign, late, sporadic."[1]

A vivid description of the Phoenicians' trade at the time of Tyre's prosperity is given by Ezekiel (xxvii. 12–25), and it shows how extensive were their commercial relations not only by sea, but by land as well. It was they who distributed to the rest of the world the wares of Egypt and Babylonia (Herod. i. 1). From the lands of the Euphrates and Tigris regular trade-routes led to the Mediterranean with trading-stations on the way, several of which are mentioned by Ezekiel (xxvii. 23). In Egypt the Phoenician merchants soon gained a foothold; they alone were able to maintain a profitable trade in the anarchic times of the XXIInd and XXIIIrd Dynasties (825–650 B.C.), when all other foreign merchants were frightened away. Though there were never any regular colonies of Phoenicians in Egypt, the Tyrians had a quarter of their own in Memphis (Herod. ii. 112). The Arabian caravan-trade in perfume, spices and incense passed through Phoenician hands on its way to Greece and the West (Herod. iii. 107); these articles of commerce were mainly produced not in Arabia, but in East Africa and India, and the trade had its centre in the wealthy state of Sheba in Yemen. Between Israel and Phoenicia the relations naturally were close; the former provided certain necessaries of life, and received in exchange articles of luxury and splendour (Ezek. xxvii. 16–18).[2] Israelite housewives sold their homespun to Phoenician pedlars (Prov. xxxi. 24 R.V.M.); in Jerusalem Phoenician merchants and money-lenders had their quarter (Zeph. i. 11), and after the Return we hear of Tyrians selling fish and all manner of ware in the city (Neh. xiii. 16), and introducing other less desirable imports, such as foreign cults (Isa. lxv. 11). The Phoenician words which made their way into Greek at an early period indicate the kind of goods in which the Phoenicians traded with the West, or made familiar through their commerce; the following are some of them—*χρυσός, χιτών, βύσσος, ὀθόνη, μύῤῥα, νάβλα, κύπρος, φῦκος, μνᾶ, παλλακίς, βαιτύλος*. Another valuable article of commerce which the Phoenicians brought into the market was amber. They can hardly have fetched it themselves from the Baltic or the North Sea; it came to them by two well-marked routes, one from the Baltic to the Adriatic, the other up the Rhine and down the Rhone. A deposit of amber has also been found in the Lebanon, and perhaps the Phoenicians worked this and concealed its origin.

[1] Burrows, *Discoveries in Crete* (1907), 140 sqq. It may be noted that the traditional or conjectural dates based upon the list of the Thalassocracies preserved by Eusebius carry us back to the 12th century B.C. See Professor John L. Myres's essay referred to above, § iii. (4).

[2] See Eupolemus (140–100 B.C.) quoted by Alexander Polyhistor, who, in a supposed letter from Solomon to the king of Tyre, mentions the food-supplies required by the Tyrians and promised from Palestine (*Fr. Hist. Gr.* iii. 226).

The Phoenician colonies were all supposed to have been founded from Tyre: with regard to the colonies in Cyprus and north Africa this was undoubtedly true. Cyprus possessed resources of timber and copper which could not fail to tempt the keen-eyed traders across the water, who made Citium (from Kittim, the name of the original non-Semitic inhabitants) their chief settlement, and thence established themselves in Idalium, Tamassus, Lapethus, Larnaka, Qarth-ḥadasht (Karti-hadasti) and other towns. In the inscriptions of the 4th to 3rd centuries, the Phoenician potentates in the island call themselves "kings of Kition and Idalion" (*NSI.* pp. 55-89). But the Phoenician rule was not so ancient as used to be supposed. At an early period Greeks from the south coast of Asia Minor had settled in Cyprus before the Phoenicians founded any colonies there; and it is noticeable that in the Assyrian tribute-lists of the latter half of the 7th century (*KB.* ii. pp. 149, 241) not one of the ten Cyprian kings mentioned appears to be Phoenician by name. Menander states (Jos. *Ant.* ix. 14, 2) that the kings of Tyre ruled over Cyprus at the close of the 8th century; but a clear proof that the Phoenician rule was neither ancient nor uninterrupted is given by the fact that the Cyprian Greeks took the trouble to invent a Greek cuneiform character (*Cypriote*) modelled on the Assyrian.

Homer represents the Phoenicians as present in Greek waters for purposes of traffic, but not as settlers (*Il.* xxiii. 744). They occupied trading-stations on some of the Aegean islands and on the Isthmus of Corinth. One of their objects was the collection of murex, of which an enormous supply was needed for the dyeing industry; specially famous was the purple of the Laconian waters, the isles of Elishah of Ezek. xxvii. 7. But a great deal of what was formerly assigned to Phoenician influence in the Aegean at an early period—pottery, ornaments and local myths—must be accounted for by the vigorous civilization of ancient Crete. In the Greek world the Phoenicians made themselves heartily detested; their characteristic passion for gain (τὸ φιλοχρήματον, Plato, *Rep.* iv. 435 E.) was not likely to ingratiate them with those who were compelled to make use of their services while they suffered from their greed.

Farther west in the Mediterranean Phoenician settlements were planted first in Sicily, on the south coast, at Heraclea or Ras Melqarth; the islands between Sicily and Africa, Melita (Malta) on account of its valuable harbour, Gaulus and Cossura were also occupied (Diod. v. 12); and a beginning was made with the colonization of Sardinia and Corsica; but farther west still, and on the Atlantic coasts to the right and left of the straits, more permanent colonies were established. It was the trade with Tarshish, *i.e.* the region of Tartessus in south-west Spain, which contributed most to the Phoenicians' wealth; for in this region they owned not only profitable fisheries, but rich mines of silver and other metals. The profits of the trade were enormous; it was said that even the anchors of ships returning from Spain were made of silver (Diod. v. 35). From Gadeira (Punic *Gādēr*, Lat. *Gades*, now Cadiz), the town which they built on an island near the mouth of the Guadalquiver, the Sidonian ships ventured farther on the ocean and drew tin from the mines of north-west Spain or from the richer deposits in the Cassiterides, *i.e.* the Tin Islands. These were discovered to be, not a part of Britain as was imagined at first, but a separate group by themselves, now known as the Scillies; hence it is improbable that the Phoenicians ever worked the tin-mines in Cornwall.

The rich trade with Spain led to the colonization of the West. Strabo dates the settlements beyond the Pillars of Hercules soon after the Trojan War (i. 3, 2), in the period of Tyre's first expansion. Lixus in Mauretania, Gades and Utica, are said to have been founded, one after the other, as far back as the 12th century B.C. Most of the African colonies were no doubt younger; we have traditional dates for Aoza (887-855) and Carthage (813). A large part of North-west Africa was colonized from Phoenicia; owing to these first settlers, and after them to the Carthaginians, the Phoenician language became the prevailing one, just as Latin and Arabic did in later times, and the country assumed quite a Phoenician character.

In the days of Tyre's greatness her power rested directly on the colonies, which, unlike those of Greece, remained subject to the mother-city, and paid tithes of their revenues to its chief god, Melqarth, and sent envoys annually to his feast. Then at the beginning of the 8th century B.C. the colonial power of Tyre began to decline; on the mainland and in Cyprus the Assyrians gained the upper hand; in the Greek islands the Phoenicians had already been displaced to a great extent by the advancing tide of Dorian colonization. But as Tyre decayed in power the colonies turned more and more to Carthage as their natural parent and protector. For effective control over a colonial empire Carthage had the advantage of situation over far-away Tyre; the traditional bonds grew lax and the ancient dues ceased to be paid, though as late as the middle of the 6th century Carthage rendered tithes to the Tyrian Melqarth. And the mother-country cherished its claims long after they had lost reality; in the 2nd century B.C., for example, Sidon stamped her coins with the legend, "Mother of Kambē (*i.e.* Carthage), Hippo, Kition, Tyre" (*NSI.* p. 352).

Manufactures, Inventions, Art.—From an early date the towns of the Phoenician coast were occupied, not only with distributing the merchandise of other countries but with working at industries of their own; especially purple-dyeing and textile fabrics (*Il.* vi. 289 sqq.), metal work in silver, gold and electrum (*Il.* xxiii. 741 sqq.; *Od.* iv. 615 sqq., xv. 458 sqq.), and glass-work, which had its seat at Sidon. The iron and copper mines of Cyprus (not Sidon, as Homer implies, *Od.* xv. 424) furnished the ore which was manufactured into articles of commerce.[1] Egyptian monuments frequently mention the vessels of gold and silver, iron and copper, made by the Ḍahi, *i.e.* the Phoenicians (W. M. Müller, *As. u. Eur.* 306); and in Cyprus and at Nimrud bronze and silver paterae have been found, engraved with Egyptian designs, the work of Phoenician artists (see table-cases C and D in the Nimrud gallery of the Brit. Mus.). The invention of these various arts and industries was popularly ascribed to the Phoenicians, no doubt merely because Phoenician traders brought the products into the market. But dyeing and embroidery probably came from Babylon in the first instance; glass-making seems to have been borrowed from Egypt; the invention of arithmetic and of weights and measures must be laid to the credit of the Babylonians. The ancients believed that the Phoenicians invented the use of the alphabet (*e.g.* Pliny, *N.H.* v. 13, cf. vii. 57; Lucan, *Bell. Civ.* iii. 220 seq.); but it is unlikely that any genuine tradition on the subject existed, and though the Phoenician theory has found favour in modern times it is open to much question. The Phoenicians cannot be said to have invented any of the arts or industries, as the ancient world imagined; but what they did was something hardly less meritorious: they developed them with singular skill, and disseminated the knowledge and use of them.

The art of Phoenicia is characterized generally by its dependence upon the art of the neighbouring races. It struck out no original line of its own, and borrowed freely from foreign, especially Egyptian, models. Remains of sculpture, engraved bronzes and gems, show clearly the source to which the Phoenician artists went for inspiration; for example, the uraeus-frieze and the winged disk, the *ankh* or symbol of life, are Egyptian designs frequently imitated. It was in the times of the Persian monarchy that Phoenician art reached its highest development, and to this period belong the oldest sculptures and coins that have come down to us. A characteristic specimen of the former is the stele of Yeḥaw-milk, king of Gebal (*CIS.* i. 1), in which the king is represented in Persian dress, and the goddess to whom he is offering a bowl looks exactly like an Egyptian Isis-Hathor; the inscription mentions the various objects of bronze and gold, engraved work and temple furniture, which the king dedicated. The whole artistic movement in Phoenicia may be divided into two great periods: in the first, from the earliest times to the 4th century B.C., Egyptian influence and then Babylonian or Asiatic influence is predominant, but the national element is strongly marked; while in the second, Greek influence has obtained the mastery, and the native element, though making itself felt, is much less obtrusive. Throughout these periods works of art, such as statues of the gods and sarcophagi, were imported direct at first from Egypt and afterwards mainly from Rhodes. The oldest example of native sarcophagi are copied from Egyptian mummy-cases, painted with colours and ornamented with carvings in low relief; towards and during the Greek period the contours of the body begin to be marked more clearly on the cover. The finest sarcophagi that have been found in the necropolis of Sidon (now in the Imperial Museum, Constantinople) are not Phoenician at all, but exquisite specimens of Greek art. The Phoenicians spent much care on their burial-places, which have furnished the most important

[1] Traces of ancient mining for iron have been found in the Lebanon; cf. LXX, 1 Kings ii. 46c (ed. Swete), which has been taken to refer to this quarrying in search of iron; Jer. xv. 12. See Benzinger on 1 Kings ix. 19.

monuments left to us. The tombs are subterranean chambers of varied and often irregular form, sometimes arranged in two storeys, sometimes in several rows one behind the other. While in early times a mere perpendicular shaft led to these excavations, at a later date stairs were constructed down to the chambers. The dead were buried either in the floor (often in a sarcophagus), or, according to later custom, in niches. The mouths of the tombs were walled up and covered with slabs, and occasionally cippi (Phoen. *maṣṣēbōth*) were set up to mark the spot. The great sepulchral monuments, popularly called *maghāzil, i.e.* "spindles," above the tombs near Amrīt, have peculiarities of their own; some of them are adorned with lions at the base and with roofs of pyramidal shape. Besides busts and figurines, which belong as a rule to the Greek period, the smaller objects usually found are earthen pitchers and lamps, glass-wares, tesserae and gems. Of buildings which can be called architectural few specimens now exist on Phoenician soil, for the reason that for ages the inhabitants have used the ruins as convenient quarries. Not a vestige remains of the great sanctuary of Melqarth at Tyre; a few traces of the temple of Adonis near Byblus were discovered by Renan, and a peculiar mausoleum, Burj al-Bezzāq, is still to be seen near Amrit; recent excavations at Bostan esh-Shēkh near Sidon have unearthed parts of the enclosure or foundations of the temple of Eshmun (*NSI.* p. 401); the conduits of Ras el-'Ain, south of Tyre, are considered to be of ancient date. With regard to the plan and design of a Phoenician temple, it is probable that they were in many respects similar to those of the temple at Jerusalem, and the probability is confirmed by the remains of a sanctuary near Amrīt, in which there is a cella standing in the midst of a large court hewn out of the rock, together with other buildings in an Egyptian style. The two pillars before the porch of Solomon's temple (1 Kings vii. 21) remind us of the two pillars which Herodotus saw in the temple of Melqarth at Tyre (Herod. ii. 44), and of those which stood before the temples of Paphos and Hierapolis (see W. R. Smith, *Rel. of Sem.*[1] p. 468 seq.).

Religion.—Like the Canaanites of whom they formed a branch, the Phoenicians connected their religion with the great powers and processes of nature.[1] The gods whom they worshipped belonged essentially to the earth; the fertile field, trees and mountains, headlands and rivers and springs, were believed to be inhabited by different divinities, who were therefore primarily local, many in number, with no one in particular supreme over the rest.

The Phoenician Gods.

It seems, however, that as time went on some of them acquired a more extended character; thus Ba'al and Astarte assumed celestial attributes in addition to their earthly ones, and the Tyrian Melqarth combined a celestial with a marine aspect.[2] The gods in general were called *'elōnīm, 'elīm*; Plautus uses *alonium valonuth* for "gods and goddesses" (*Poen.* v. 1, 1). These plurals go back to the singular form 'El, the common Semitic name for God; but neither the singular nor the plural is at all common in the inscriptions (*NSI.* pp 24, 41, 51); 'El by itself has been found only once;[3] the fem. 'Elath is also rare (ibid. pp. 135, 158). The god or goddess was generally called the Ba'al or Ba'alath of such and such a place, a title which was used not only by the Canaanites, but by the Aramaeans (Be'el) and Babylonians (Bel) as well. There was no one particular god called Baal; the word is not a proper name but an appellative, a description of the deity as *owner* or *mistress*; and the same is the case with Milk or Melek, 'Adon, 'Amma, which mean *king, lord, mother*. The god himself was unnamed or had no name. Occasionally we know what the name was; the Baal of Tyre was Melqarth (Melkarth), which again means merely "king of the city"; similarly among the Aramaeans the Ba'al of Harran was the moon-god Sin. As each city or district had its own Ba'al, the author of its fertility, the "husband" (a common meaning of *ba'al*) of the land which he fertilized, so there were many Ba'als, and the Old Testament writers could allude to the Ba'ālim of the neighbouring Canaanites. Sometimes the god received a distinguishing attribute which indicates an association not with any particular place, but with some special characteristic; the most common forms are Ba'al-ḥammān, the chief deity of Punic north Africa, perhaps "the glowing Ba'al," the god of fertilizing warmth, and Ba'al-shamēm, "Ba'al of the heavens."[4] The latter deity was widely venerated throughout the North-Semitic world; his name, which does not appear in the Phoenician inscriptions before the 3rd century B.C., implies perhaps a more universal conception of deity than existed in the earlier days.[5] The worship of the female along with the male principle was a strongly marked feature of Phoenician religion. To judge from the earliest evidence on the subject, the Ba'alath of Gebal or Byblus, referred to again and again in the Amarna letters (*Bilit ša Gubla*, Nos. 55-110), must have been the most popular of the Phoenician deities, as her sanctuary was the oldest and most renowned. The *mistress of Gebal* was no doubt 'Ashtart (Astartē in Greek, 'Ashtōreth in the Old Testament, pronounced with the vowels of *bōsheth*, "shame"), a name which is obviously connected with the Babylonian Ishtar, and, as used in Phoenician, is practically the equivalent of "goddess." She represented the principle of fertility and generation; references to her cult at Gebal, Sidon, Ashkelon, in Cyprus at Kition and Paphos, in Sicily at Eryx, in Gaulus, at Carthage, are frequent in the inscriptions and elsewhere. The common epithets Κύπρις and Κυθέρεια (of Kuthera in Cyprus), Cypria and Paphia, show that she was identified with Aphrodite and Venus. Though not primarily a moon-goddess, she sometimes appears in this character (Lucian, *Dea syr.* § 4; Herodian v. 6, 10), and Herodotus describes her temple at Ashkelon as that of the heavenly Aphrodite (i. 105). We find her associated with Ba'al and called "the name of Ba'al," *i.e.* his manifestation, though this rendering is disputed, and some scholars prefer "'Ashtart of the heaven of Ba'al" (*NSI.* p. 37). Another goddess, specially honoured at Carthage, is Tanith (pronunciation uncertain); nothing is known of her characteristics; she is regularly connected with Ba'al on the Carthaginian votive tablets, and called "the face of Ba'al," *i.e.* his representative or revelation, though again some question this rendering as too metaphysical, and take "face of Ba'al" to be the name of a place, like Penu'el ("face of 'El"). Two or three other deities may be mentioned here: Eshmun, the god of vital force and healing, worshipped at Sidon especially, but also at Carthage and in the colonies, identified by the Greeks with Asclepius; Melqarth, the patron deity of Tyre, identified with Heracles; Reshef or Reshūf, the "flame" or "lightning" god, especially popular in Cyprus and derived originally from Syria, whom the Greeks called Apollo. A tendency to form a distinct deity by combining the attributes of two produced such curious fusions as Milk-'ashtart, Milk-ba'al, Milk-'osir, Eshmun-melqarth, Melqarth-reṣef, &c. As in the case of art and industries, so in religion the Phoenicians readily assimilated foreign ideas. The influence of Egypt was specially strong (*NSI.* pp. 62, 69, 148, 154); thus the Astarte represented on the stele of Yeḥaw-milk, mentioned above, has all the appearance of Isis, who, according to the legend preserved by Plutarch (*de Is. et Os.* 15), journeyed to Byblus, where she was called Astarte. The Phoenician settlers at the Peiraeus worshipped the Assyrian Nergal, and their proper names are compounded with the names of Babylonian and Arabian deities (*NSI.* p. 101). Closer intimacy with the Greek world naturally brought about modifications in the character of the native gods, which became apparent when Ba'al of Sidon or Ba'al-shamēm was identified with Zeus, Tanith with Demeter or Artemis, 'Anath with Athena, &c.; the notion of a supreme Ba'al, which finds expression in the Greek *βῆλος* and *βααλτίς* or *βήλθης* (the goddess of Byblus), was no doubt encouraged by foreign influences. On the other hand, the Phoenicians produced a considerable effect upon Greek and Roman religion, especially from the religious centres in Cyprus and Sicily. A great number of divinities are known only as elements in proper names, *e.g. Sakun*-yathon (Sanchuniathon), 'Abd-*sasom*, *Ṣed*-yathon, and fresh ones are continually being discovered. It was the custom among the Phoenicians, as among other Semitic nations, to use the names of the gods in forming proper names and thus to express devotion or invoke favour; thus Ḥanni-ba'al, 'Abd-melqarth, Ḥanni-'ashtart, Eshmun-'azar. The proper names further illustrate the way in which the relation of man to God was regarded; the commonest forms are *servant* ('abd, *e.g.* 'Abd-'ashtart), *member* or *limb* bod, *e.g.* Bod-melqarth), client or *guest* (ger, *e.g.* Ger-'eshmun); the religious idea of the *guest* of a deity had its origin in the social custom of extending hospitality to a stranger and in the old Semitic right of sanctuary. The interpretation of such names as 'Abi-ba'al (father of Ba'al), Ḥimilkath (brother of Milkath), Ḥiram (brother of the exalted one) is not altogether certain, and can hardly be discussed here.[6]

Probably like other Canaanites the Phoenicians offered worship "on every high hill and under every green tree"; but to judge from the allusions to sanctuaries in the inscriptions and elsewhere, the Ba'al or 'Ashtart of a place was usually worshipped at a temple, which consisted of a court or enclosure and a roofed shrine with a portico or pillared hall at the entrance.

Sacred Objects and Worship.

In the court sometimes stood a conical stone, probably the symbol of Astarte, as on the Roman coins of Byblus (illustrated in Rawlinson, *Phoenicia*, 146, Perrot et Chipiez, *Hist. de l'art*, iii. 60; see also Ohnefalsch-Richter, *Cyprus*, pl. lvi., the temenos at Idalion). Stone or bronze images of the gods were set up in the sanctuaries (*NSI.* Nos. 13 seq., 23-27, 30, &c.); and besides these the *baetylia* (meteoric stones) which were regarded as symbols of the gods. Pillars, again, had a prominent place in the court or before the shrine (*naṣab*, ibid. pp. 102 seq.); but it is not known whether the sacred pole (*'ashērah*), an invariable feature of a Canaanite sanctuary, was usual in a Phoenician temple (ibid. pp. 50 seq.). The

The Phoenician colonies were all supposed to have been founded from Tyre: with regard to the colonies in Cyprus and north Africa this was undoubtedly true. Cyprus possessed resources of timber and copper which could not fail to tempt the keen-eyed traders across the water, who made Citium (from Kittim, the name of the original non-Semitic inhabitants) their chief settlement, and thence established themselves in Idalium, Tamassus, Lapethus, Larnaka, Qarth-ḥadasht (Karti-hadasti) and other towns. In the inscriptions of the 4th to 3rd centuries, the Phoenician potentates in the island call themselves "kings of Kition and Idalion" (*NSI.* pp. 55-89). But the Phoenician rule was not so ancient as used to be supposed. At an early period Greeks from the south coast of Asia Minor had settled in Cyprus before the Phoenicians founded any colonies there; and it is noticeable that in the Assyrian tribute-lists of the latter half of the 7th century (*KB.* ii. pp. 149, 241) not one of the ten Cyprian kings mentioned appears to be Phoenician by name. Menander states (Jos. *Ant.* ix. 14, 2) that the kings of Tyre ruled over Cyprus at the close of the 8th century; but a clear proof that the Phoenician rule was neither ancient nor uninterrupted is given by the fact that the Cyprian Greeks took the trouble to invent a Greek cuneiform character (*Cypriote*) modelled on the Assyrian.

Homer represents the Phoenicians as present in Greek waters for purposes of traffic, but not as settlers (*Il.* xxiii. 744). They occupied trading-stations on some of the Aegean islands and on the Isthmus of Corinth. One of their objects was the collection of murex, of which an enormous supply was needed for the dyeing industry; specially famous was the purple of the Laconian waters, the isles of Elishah of Ezek. xxvii. 7. But a great deal of what was formerly assigned to Phoenician influence in the Aegean at an early period—pottery, ornaments and local myths—must be accounted for by the vigorous civilization of ancient Crete. In the Greek world the Phoenicians made themselves heartily detested; their characteristic passion for gain (τὸ φιλοχρήματον, Plato, *Rep.* iv. 435 E.) was not likely to ingratiate them with those who were compelled to make use of their services while they suffered from their greed.

Farther west in the Mediterranean Phoenician settlements were planted first in Sicily, on the south coast, at Heraclea or Ras Melqarth; the islands between Sicily and Africa, Melita (Malta) on account of its valuable harbour, Gaulus and Cossura were also occupied (Diod. v. 12); and a beginning was made with the colonization of Sardinia and Corsica; but farther west still, and on the Atlantic coasts to the right and left of the straits, more permanent colonies were established. It was the trade with Tarshish, *i.e.* the region of Tartessus in south-west Spain, which contributed most to the Phoenicians' wealth; for in this region they owned not only profitable fisheries, but rich mines of silver and other metals. The profits of the trade were enormous; it was said that even the anchors of ships returning from Spain were made of silver (Diod. v. 35). From Gadeira (Punic *Gādēr*, Lat. *Gades*, now Cadiz), the town which they built on an island near the mouth of the Guadalquiver, the Sidonian ships ventured farther on the ocean and drew tin from the mines of north-west Spain or from the richer deposits in the Cassiterides, *i.e.* the Tin Islands. These were discovered to be, not a part of Britain as was imagined at first, but a separate group by themselves, now known as the Scillies; hence it is improbable that the Phoenicians ever worked the tin-mines in Cornwall.

The rich trade with Spain led to the colonization of the West. Strabo dates the settlements beyond the Pillars of Hercules soon after the Trojan War (i. 3, 2), in the period of Tyre's first expansion. Lixus in Mauretania, Gades and Utica, are said to have been founded, one after the other, as far back as the 12th century B.C. Most of the African colonies were no doubt younger; we have traditional dates for Aoza (887-855) and Carthage (813). A large part of North-west Africa was colonized from Phoenicia; owing to these first settlers, and after them to the Carthaginians, the Phoenician language became the prevailing one, just as Latin and Arabic did in later times, and the country assumed quite a Phoenician character.

In the days of Tyre's greatness her power rested directly on the colonies, which, unlike those of Greece, remained subject to the mother-city, and paid tithes of their revenues to its chief god, Melqarth, and sent envoys annually to his feast. Then at the beginning of the 8th century B.C. the colonial power of Tyre began to decline; on the mainland and in Cyprus the Assyrians gained the upper hand; in the Greek islands the Phoenicians had already been displaced to a great extent by the advancing tide of Dorian colonization. But as Tyre decayed in power the colonies turned more and more to Carthage as their natural parent and protector. For effective control over a colonial empire Carthage had the advantage of situation over far-away Tyre; the traditional bonds grew lax and the ancient dues ceased to be paid, though as late as the middle of the 6th century Carthage rendered tithes to the Tyrian Melqarth. And the mother-country cherished its claims long after they had lost reality; in the 2nd century B.C., for example, Sidon stamped her coins with the legend, "Mother of Kambē (*i.e.* Carthage), Hippo, Kition, Tyre" (*NSI.* p. 352).

Manufactures, Inventions, Art.—From an early date the towns of the Phoenician coast were occupied, not only with distributing the merchandise of other countries but with working at industries of their own; especially purple-dyeing and textile fabrics (*Il.* vi. 289 sqq.), metal work in silver, gold and electrum (*Il.* xxiii. 741 sqq.; *Od.* iv. 615 sqq., xv. 458 sqq.), and glass-work, which had its seat at Sidon. The iron and copper mines of Cyprus (not Sidon, as Homer implies, *Od.* xv. 424) furnished the ore which was manufactured into articles of commerce.[1] Egyptian monuments frequently mention the vessels of gold and silver, iron and copper, made by the Ḍahi, *i.e.* the Phoenicians (W. M. Müller, *As. u. Eur.* 306); and in Cyprus and at Nimrud bronze and silver paterae have been found, engraved with Egyptian designs, the work of Phoenician artists (see table-cases C and D in the Nimrud gallery of the Brit. Mus.). The invention of these various arts and industries was popularly ascribed to the Phoenicians, no doubt merely because Phoenician traders brought the products into the market. But dyeing and embroidery probably came from Babylon in the first instance; glass-making seems to have been borrowed from Egypt; the invention of arithmetic and of weights and measures must be laid to the credit of the Babylonians. The ancients believed that the Phoenicians invented the use of the alphabet (*e.g.* Pliny, *N.H.* v. 13, cf. vii. 57; Lucan, *Bell. Civ.* iii. 220 seq.); but it is unlikely that any genuine tradition on the subject existed, and though the Phoenician theory has found favour in modern times it is open to much question. The Phoenicians cannot be said to have invented any of the arts or industries, as the ancient world imagined; but what they did was something hardly less meritorious: they developed them with singular skill, and disseminated the knowledge and use of them.

The art of Phoenicia is characterized generally by its dependence upon the art of the neighbouring races. It struck out no original line of its own, and borrowed freely from foreign, especially Egyptian, models. Remains of sculpture, engraved bronzes and gems, show clearly the source to which the Phoenician artists went for inspiration; for example, the uraeus-frieze and the winged disk, the *ankh* or symbol of life, are Egyptian designs frequently imitated. It was in the times of the Persian monarchy that Phoenician art reached its highest development, and to this period belong the oldest sculptures and coins that have come down to us. A characteristic specimen of the former is the stele of Yeḥaw-milk, king of Gebal (*CIS.* i. 1), in which the king is represented in Persian dress, and the goddess to whom he is offering a bowl looks exactly like an Egyptian Isis-Hathor; the inscription mentions the various objects of bronze and gold, engraved work and temple furniture, which the king dedicated. The whole artistic movement in Phoenicia may be divided into two great periods: in the first, from the earliest times to the 4th century B.C., Egyptian influence and then Babylonian or Asiatic influence is predominant, but the national element is strongly marked; while in the second, Greek influence has obtained the mastery, and the native element, though making itself felt, is much less obtrusive. Throughout these periods works of art, such as statues of the gods and sarcophagi, were imported direct at first from Egypt and afterwards mainly from Rhodes. The oldest example of native sarcophagi are copied from Egyptian mummy-cases, painted with colours and ornamented with carvings in low relief; towards and during the Greek period the contours of the body begin to be marked more clearly on the cover. The finest sarcophagi that have been found in the necropolis of Sidon (now in the Imperial Museum, Constantinople) are not Phoenician at all, but exquisite specimens of Greek art. The Phoenicians spent much care on their burial-places, which have furnished the most important

[1] Traces of ancient mining for iron have been found in the Lebanon; cf. LXX, 1 Kings ii. 46c (ed. Swete), which has been taken to refer to this quarrying in search of iron; Jer. xv. 12. See Benzinger on 1 Kings ix. 19.

from Arabia, delighting the gods with his fragrance and rising from the sinking flames of the morning glow, was enough to suggest most of the traits materialized in the classical pictures of the phoenix. That the *benu* is the prototype of the phoenix is further confirmed by the fact that the former word in Egyptian means also "palm-tree," just as the latter does in Greek. The very various periods named make it probable that the periodical return of the phoenix belongs only to vulgar legend, materializing what the priests knew to be symbolic. Of the birds of the heron family the gorgeous colours and plumed head spoken of by Pliny and others would be least inappropriate to the purple heron (*Ardea purpurea*), with which, or with the allied *Ardea cinerea*, it has been identified by Lepsius and Peters (*Alteste Texte des Todtenbuchs*, 1867, p. 51). But the golden and purple hues described by Herodotus may be the colours of sunrise rather than the actual hues of the purple heron. How Herodotus came to think that the bird was like an eagle is quite unexplained; perhaps this is merely a slip of memory.

Many commentators still understand the word חול, *chôl*, in Job xxix. 18 (A.V. "sand") of the phoenix. This interpretation is perhaps as old as the (original) Septuagint, and is current with the later Jews. Among the Arabs the story of the phoenix was confused with that of the salamander; and the samand or samandal (Damiri, ii. 36 seq.) is represented sometimes as a quadruped, sometimes as a bird. It was firmly believed in, for the incombustible cloths woven of flexible asbestos were popularly thought to be made of its hair or plumage, and were themselves called by the same name (cf. Yaqut i. 529, and Dozy, *s.v.*). The *'ankā* (Pers. *sîmurgh*), a stupendous bird like the roc (rukh) of Marco Polo and the *Arabian Nights*, also borrows some features of the phoenix. According to Kazwînî (i. 420) it lives 1700 years, and when a young bird is hatched the parent of opposite sex burns itself alive. In the book of *Kalila and Dimna* the *sîmūr* or *'ankā* is the king of birds, the Indian *garūda*, on whom Vishnu rides.

PHOENIX, the capital of Arizona, U.S.A., and the county-seat of Maricopa county, situated on the Salt River, in the south central part of the state. Pop. (1890), 3152; (1900), 5544 (935 being foreign-born and 148 negroes); (1910) 11,134. It is served by the Arizona Eastern and the Sante Fé, Prescott & Phoenix railways, the former connecting at Maricopa (35 m. distant) with the Southern Pacific and the latter connecting at Ash Fork, near Prescott (194 m. distant), with the Atchison, Topeka & Santa Fé. The city is a popular winter and health resort, with a fine dry climate. The city is the see of a Protestant Episcopal bishopric. About 3 m. north of the city is the Phoenix (non-reservation) boarding-school for Indians, supported by the United States government, with an average attendance of about 700 pupils. The city lies in a great plain, in the centre of a region of pastures, gardens and orchards, the largest and most beautiful farming district of Arizona, irrigated with water stored by the great Roosevelt dam (about 70 m. north east of Phoenix). Local interests are almost entirely in agriculture, stock-raising and fruit-growing. In the surrounding region are several large ostrich farms and a small exhibition ranch. Phoenix was settled in 1870, became the county-seat on the organization of Maricopa county in 1871, was incorporated in 1881, and became the capital of Arizona in 1889.

PHOENIX ISLANDS, a group of eight small islands in the Pacific Ocean, about 3° S., and 172° W., belonging to Great Britain. They have a land area about 16 sq. m. and a population of 60. Their names are Phoenix, Gardner (Kemin), Hull, Sydney, Birnie, Enderbury, Canton (Mary) and McKean. To the north-west of the group (between the equator and 1° N.) lie two more islets—Baker and Howland. The islands were annexed by Great Britain in 1889–1892.

PHOENIXVILLE, a borough of Chester county, Pennsylvania, U.S.A., on the Schuylkill River at the mouth of French Creek, about 28 m. north-west of Philadelphia. Pop. (1890), 8514; (1900), 9196, of whom 2221 were foreign-born and 278 were negroes; (1906 estimate), 9604. It is served by the Pennsylvania (Schuylkill division) and the Philadelphia & Reading railways, and by electric railway to Spring City (pop. in 1900, 2566), 5 m. north-west of Phoenixville on the Schuylkill. Phoenixville is chiefly a manufacturing borough. Its blast-furnaces and iron mills were long among the largest in the country, and the manufacture of steel is still the borough's predominant industry. Phoenixville was settled in 1732, and was incorporated in 1849.

PHONETICS (Gr. φωνή, voice), the science of speech-sounds and the art of pronunciation. In its widest sense it is the "science of voice," dealing not only with articulate, but also with the inarticulate sounds of animals as well as men. The originally synonymous term, "phonology," is now restricted to the history and theory of sound-changes. The most obvious of the practical applications of phonetics is to the acquisition of a correct pronunciation of foreign languages. But its applications to the study of the native language are not less important: it is only by the help of phonetics that it is possible to deal effectively with vulgarisms and provincialisms of pronunciation and secure uniformity of speech; and it is only on a phonetic basis that the deaf and dumb can be taught articulate speech. From a more theoretical point of view phonetics is, in the first place, the science of linguistic observation. Without phonetic training the dialectologist, and the missionary who is confronted with a hitherto unwritten language, can neither observe fully nor record accurately the phenomena with which they have to deal. These investigations have greatly widened the scope of the science of language. The modern philologist no longer despises colloquial and illiterate forms of speech. On the contrary, he considers that in them the life and growth of language is seen more clearly than in dead literary languages, on whose study the science of comparative philology was at first exclusively built up. It was not till philologists began to ask what were the real facts underlying the comparisons of the written words in Sanskrit, Greek, Latin, and the other Indo-European languages, embodied in such generalizations as Grimm's Law, that "letter-science" developed into "sound-science" (phonology). The rise and decay of inflexions, and the development of grammatical forms generally, are, from the formal point of view, mainly phonetic problems; and phonetics enters more or less into every department of historical and comparative grammar.

Methods of Study and Investigation.—Phonetics is the science of speech-sounds. But sounds may be considered from two opposite points of view—the *organic* and the *acoustic*. From the organic point of view a sound is the result of certain actions and positions of the organs of speech, as when we define *f* as a lip-teeth (dento-labial) consonant. This is the point of view of the speaker of a language. To the hearer, on the other hand, *f* is not a lip-teeth, but a hiss consonant similar to that denoted by *th*. This is the acoustic point of view. Theoretically, the organic study of phonetics is a branch of anatomy and physiology: that part of these sciences which deals with the organs of speech (see MOUTH) and their functions (see VOICE); while, from the opposite point of view, the study of phonetics is based on that branch of physical science known as acoustics (see SOUND), together with the anatomy and physiology of the organs of Hearing (*q.v.*).

Unfortunately, this basis is still imperfect. The principles of acoustics are well established, and we know much about the anatomy of the ear. But how the ear transmits to the brain the impression of sound is still a mystery. Again, although the mechanism of the vowel is clear enough, there is still no generally received acoustic theory of their formation. In fact, from the physical science point of view there is as yet no science of phonetics.

The real function of phonetics is philological and literary. The only sound basis of a theoretical knowledge of phonetics is the practical mastery of a limited number of sounds—that is to say, of the sounds which are already familiar to the learner in his own language. It is evident that the more familiar a sound is, the easier it is to gain insight into its mechanism and to recognize it when heard. It is indispensable to cultivate both the organic and the acoustic sense. These processes we are continually carrying out in ordinary conversation. All, therefore, that we have to do in dealing with native sounds is to develop this unconscious organic and acoustic sense into a conscious and analytic one. The first step is to learn to isolate each sound: to

pronounce it, as far as possible, apart from its context; and to preserve it unchanged through every variation of length and force, and in every combination of sounds. The next step is to analyse its formation. Let the student, for instance, compare the two consonants in such a word as *five* by isolating and lengthening them till he can both hear and feel the voice-vibration in the second one. In the same way let him learn to feel the changes in the position of the tongue and lips in passing from one vowel to another. When the native sounds have been thoroughly studied in this way, the learner will proceed to foreign sounds, deducing each new sound from those which are already familiar to him.

The natural method of learning sounds is mainly a subjective one. We listen patiently till our ears are steeped, as it were, in the sound; and then, after repeated trials, we hit on the exact position of the organs of speech by which we can reproduce the sound to the speaker's satisfaction. But the natural method admits also of objective control and criticism of the movements of the lips and jaws by direct observation. The movements and positions of the tongue and soft palate, and other modifications of the mouth and throat passages are also more or less accessible to observation—in the case of self-observation with the help of a small mirror held in the hand. If the mirror is small enough to go into the mouth, and is fixed obliquely to a handle, so that it can be held against the back of the mouth at such an angle as to reflect a ray of light down the throat, we have the *laryngoscope*. Laryngoscopy has confirmed earlier results, and has also added to our knowledge of the throat sounds. But, on the other hand, it has been a fruitful source of error. There has been great discrepancy between the results obtained by different observers; and many results which were at first received with implicit confidence for their supposed rigorously scientific and objective character have been found to be worthless. It seemed at first as if Röntgen's discovery of the so-called X-rays would meet the want of a means of direct observation of the positions of the tongue, not lengthways, but from the side, as also of the interior of the throat. But although the cheeks are to a certain extent transparent to these rays, the shadow of the tongue projected on the screen is too indistinct to be of any use.

But there are other methods besides those of direct observation by which the positions of the tongue may be objectively determined and measured with more or less accuracy. The interior of the mouth may be explored by the fingers. If the little finger is held against the gums during the articulation of the vowels in *it*, *ate*, *at*, the difference in the height of the tongue will at once become apparent: in the formation of the first vowel the tongue is pressed strongly against the artificial palate, while in that of the second it only just touches it, and in that of the third it does not touch at all.

Several forms of apparatus have been devised for a more accurate determination of the positions of the tongue and the other movable organs of speech. The best results hitherto as regards the vowel-positions have been obtained by Grandgent, who uses disks of card-board of various sizes fixed to silver wires. A full description of this and other methods will be found in Scripture's *Elements of Experimental Phonetics*.

There are other methods whose results are obtained only indirectly. The simplest of these are the *palatographic*, by which are obtained "palatograms" recording the contact of the tongue with the palate. The apparatus most generally used consists of a thin, shell-like artificial palate, which is covered with chalk and placed in the mouth; when the sound is made, the articulation of the tongue is inferred from the contact-marks on the plate. This method is evidently limited in its application. It, too, has the drawback of not being applicable to the sounds formed in the back of the mouth. The outlines of palatograms are much vaguer than they appear in the published drawings of them; and it is a question whether the thickness even of the thinnest plate does not modify the record.

The methods hitherto considered are all comparatively simple. They require no special knowledge or training, and are accessible to all. But there are more elaborate methods—with which the name "experimental phonetics" is more specially connected—involving special training in practical and theoretical physics and mathematics, and requiring the help of often complicated and costly, and not easily accessible, apparatus. The investigation of the speech curves of phonograph and gramophone records is a typical example. Good examples of these methods are afforded by E. A. Meyer's investigations of vowel-quantity in English (Englische Lautdauer, Uppsala, 1903). Their characteristic feature is their delicacy, and the minuteness of their distinctions, which often go beyond the range of the human ear. Although their results are often of value, they must always be received with caution; the sources of error are so numerous.

The claims of instrumental phonetics have been so prominently brought forward of late years that they can no longer be ignored, even by the most conservative of the older generation of phoneticians. But it is possible to go too far the other way. Some of the younger generation seem to think that the instrumental methods have superseded the natural ones in the same way as the Arabic superseded the Roman numerals. This assumption has had disastrous results. It cannot be too often repeated that instrumental phonetics is, strictly speaking, not phonetics at all. It is only a help: it only supplies materials which are useless till they have been tested and accepted from the linguistic phonetician's point of view. The final arbiter in all phonetic questions is the trained ear of a practical phonetician: differences which cannot be perceived must—or at least may be—ignored; what contradicts the trained ear cannot be accepted.

Sound-Notation; Spelling Reform.—Next to the analysis of the sounds themselves, the most important problem of phonetics is their representation by means of written and printed symbols. The traditional or "nomic" orthographies of most languages are only imperfectly phonetic. And, unfortunately, of the languages in most general use, two are exceptionally unphonetic in their orthographies, French showing the greatest divergence between sound and symbol, while English shows the maximum of irregularity and arbitrariness. The German orthography is comparatively phonetic: it has hardly any silent letters, and it generally has one symbol for each sound, each symbol having only one value, the exceptions falling under a few simple rules, which are easily remembered. There are other languages which have still more phonetic orthographies, such as Spanish, Welsh and Finnish. But even the best of them are not perfect: even when they are not actually misleading, they are always inadequate. On the other hand, no system of writing is wholly unphonetic. Even in French and English there are many words whose spelling not even the most radical reformer would think of altering. In fact, all writing which has once emerged from the hieroglyphic stage is at first purely phonetic, as far as its defective means will allow. The divergence between sound and symbol which makes spelling unphonetic is the result of the retention of phonetic spellings after they have become unphonetic through changes in the pronunciation of the words themselves. Thus, such English spellings as *knight* and *wright* were still phonetic in the time of Chaucer; for at that time the initial consonants of these words were still pronounced, and the *gh* still had the sound of *ch* in German *ich*. So also *see* and *sea* are written differently, not by way of arbitrary distinction, but because they were pronounced differently till within the last few centuries—as they still are in Irish-English.

Where there is no traditional orthography, as when Old English (Anglo-Saxon) was first written down in Latin letters, spelling was necessarily phonetic; but where there is a large literature and a class of professional scribes, the influence of the traditional orthography becomes stronger, till at last the invention of printing and the diffusion of one standard dialect over a large area occupied originally by a variety of other dialects make changes of spelling as inconvenient as they were once easy and natural. The ideal orthography for printers is one which is absolutely uniform over the whole territory of the language, and absolutely unchangeable. In such orthographies as those of the present English and French there is no longer any living correspondence between sound and symbol: they are, in intention at least, wholly unphonetic; they are preserved by graphic, not by oral, tradition.

But unphoneticness has its practical limits. A purely unphonetic degradation of an originally phonetic system of writing—one in which there is absolutely no correspondence between sounds and letters—could not be mastered even by the most retentive memory: it would be even more difficult than the Chinese writing. Hence a phonetic reaction is inevitable. In the middle ages the spelling was periodically readjusted in accordance with the changes of pronunciation—as far, of course, as the imperfections of the existing orthography would allow. This adjustment went on even after the introduction of printing. In fact, it is only within the last hundred years or so that the orthographies of English and French have become fixed.

One result of this fixity is that any attempt to continue the process of adjustment assumes a revolutionary character. When, in 1849, the pioneers of the modern spelling-reform

movement—A. J. Ellis and I. Pitman—brought out the *Fonetic Nuz*, few of those who joined in the chorus of ridicule excited by the new alphabet stopped to consider that this uncouthness was purely the result of habit, and that the Authorized Version of the Bible in the spelling of its first edition would seem to us not less strange and uncouth than in the new-fangled phonotypy of Messrs Ellis and Pitman. Nor did they stop to consider that phonetics and phonetic spelling, so far from being innovations, are as old as civilization itself. The Alexandrian grammarians were not only phoneticians—they were spelling-reformers; they invented the Greek accents for the purpose of making the pronunciation of Greek easier to foreigners. The Romans, too, were phoneticians: they learnt Greek by phonetic methods, and paid great attention to niceties of pronunciation. The Sanskrit grammarians were still better phoneticians.

As a matter of fact, English spelling was still phonetic as late as the time of Shakespeare—in intention, at least. But although people still tried to write as they spoke, the inherited imperfections of their orthography made it more and more difficult for them to do so. Hence already in the 16th century a number of spelling-reformers made their appearance, including classical scholars such as Sir John Cheke, and A. Gill, who was head-master of St Paul's School in London. Gill has left us extracts from Spenser's *Faerie Queene* in phonetic spelling; but, strange to say, nothing of Shakespeare's, although he and Shakespeare were exact contemporaries. But Gill's and the other alphabets proposed were too intricate and cumbrous for popular use.

Nevertheless, some important phonetic reforms were successfully carried through, such as getting rid of most of the superfluous final *e*'s, utilizing the originally superfluous distinctions in form between *i* and *j*, *u* and *v*, by using *i*, *u* only as vowels, *j*, *v* only as consonants, instead of at random—a reform which seems to have begun in Italy. Another important reform was the introduction of *ea* and *oa*, as in *sea* and *boat*, which had hitherto been written with *ee* and *oo*, being thus confused with *see* and *boot*.

All these were as much phonetic reforms as it would be to utilize long *s* and tailed *z* (ʃ, ʒ) to denote the final consonants in *fish* and *rouge* respectively; a reform first suggested by A. J. Ellis, who was himself the first to call attention to the works of these early phoneticians and to utilize them in the investigations enshrined in his great work on *Early English Pronunciation*.

With all its defects, the present English spelling is still mainly phonetic; we can still approximately guess the pronunciation of the vast majority of words from their spelling. So when we say that English spelling is unphonetic we merely mean that it is a bad phonetic spelling; and all that spelling-reformers aim at is to make this bad into a good phonetic spelling, that is, an efficient and easy one. But the difficulties are great; and the more we know of phonetics, and the more we experiment with different systems of spelling, the more formidable do they appear. One of the difficulties, however, that is commonly supposed to stand in the way of spelling-reform is quite imaginary: namely, that it would destroy the historical and etymological value of the present system. Thus E. A. Freeman used to protest against it as "a reckless wiping out of the whole history of the language." Such critics fail to see that historical spelling, if carried out consistently, would destroy the materials on which alone history can be based; that these materials are nothing else but a series of phonetic spellings of different periods of the language, and that if a consistent historical and etymological spelling could have been kept up from the beginning, there would have been no Grimm's Law, no etymology; in short, no comparative or historical philology possible.

The advantages of beginning a foreign language in a phonetic notation are many and obvious. In the first place, the learner who has once mastered the notation and learnt to pronounce the sounds the letters stand for, is able to read off at once any text that is presented to him without doubt or hesitation, and without having to burden his memory with rules of pronunciation and spelling. Another advantage of phonetic spelling is that when the learner sees the words written in a representation of their actual spoken form he is able to recognize them at once when he hears them. And if the learner begins with the phonetic notation, and uses it exclusively till he has thoroughly mastered the spoken language, he will then be able to learn the ordinary spelling without fear of confusion, and quicker than he would otherwise have done.

Spelling-reform may be carried out with various degrees of thoroughness. After the failure of many schemes of radical reform, an attempt was made to begin with those numerous spellings which are both unphonetic and unhistorical, or are against the analogy of other traditional spellings. Accordingly, in 1881 the Philological Society of London "aproovd (*sic*) of certain partial corections (*sic*) of English spellings," which were also approved of by the American Spelling-reform Association; and a list of them was issued jointly by the two bodies, and recommended for general adoption. A similar movement has been started in France. But the general feeling appears to be that it is better to keep the ordinary spelling unchanged, and wait till it is possible to supersede it by one on a more or less independent basis.

If the existing Roman alphabet is made the basis of the new phonetic notation of any one language, the most obvious course is to select one of the various traditional representations of each sound, and use that one symbol exclusively, omitting, of course, at the same time all silent letters. A. J. Ellis's *English Glossic* is an example of such a phonetic spelling on a national basis. The following is a specimen:—

Ingglish Glosik iz veri eezi too reed. Widh proper training a cheild foar yeerz oald kan bee redili taut too reed Glosik buoks.

But a system which, like this, writes short and long vowels with totally different symbols (i, ee) is only half phonetic: it is phonetic on an unphonetic basis.

A fully phonetic system, in which, for instance, long vowels and diphthongs are expressed by consistent modifications or combinations of the symbols of the short vowels, and in which simple sounds are, as far as is reasonable and convenient, expressed by single letters instead of digraphs such as *sh*, must necessarily discard any national basis. The best basis on the whole is obtained by giving the letters their original common European sounds, *i.e.* by returning to the Late Latin pronunciation, with such modifications and additions as may be advisable. As regards the vowels at least, this Latin basis is very well preserved in German and Italian. In French, on the other hand, the Latin tradition was greatly corrupted already in the earliest period through the rapid changes which the language underwent. Thus when the Latin *u* in *luna* assumed the sound it now has in French *lune*, the symbol *u* was still kept; and when the sound *u* afterwards developed again out of the diphthong *ou*, this digraph was used to denote the sound. So when the French system of spelling came into use in England after the Norman Conquest these unphonetic symbols were introduced into English spelling, so that such a word as Old English and Early Middle English *hūs*, "house," was written *hous* in the Late Middle English of Chaucer, although the sound was still that of Scotch *hoos*, *ou* (ow) being also used to denote a true diphthong (ou) in such words as *knou*, *know*, from Old English *cnāwan*.

By returning, then, to the original values of the letters we get the "Romic" or international (Continental) basis as opposed to the Glossic or national basis. Thus the passage quoted above appears as follows in Sweet's "Broad Romic" notation:—

iŋgliʃ glosik iz veri iizi tu riid. wið propə treiniŋ ə tʃaild fɔə jiəz ould kən bii redili tɔt tu riid glosik buks.

Another important general distinction is that between "broad" and "narrow" systems of notation. A broad notation is one which makes only the practically necessary distinctions in each language, and makes them in the simplest manner possible, omitting all that is superfluous. From a practical point of view the necessary distinctions are those on which differences of meaning depend. A distinction of sound which is significant in one language may be unsignificant in another. Thus the distinction between close *é* and open *è*, *ê* is significant in French, as in *pécher*, *pêcher*; so if in French phonetic writing the former

is denoted by (e), it is necessary to find a new symbol (ɛ) for the open sound. But in languages such as English and German, where the short *e* is always open, there is no practical objection to using the unmodified (e) to denote the open sound, even if we regard (e) as the proper symbol of the close sound. And in those languages in which the short *e* is always open and the long *e* always close it is enough to mark the distinction of quantity, and leave the distinction of quality to be inferred from it (e, ee). In such a case as this it is, of course, possible to apply the principle of ignoring superfluous distinctions in the opposite way: by writing the long and short vowels in such a language (*e*, ɛ), leaving the quantity to be inferred from the quality. But the former method is the more convenient, as it does not require any new letter. The "broad" principle is especially convenient in writing diphthongs. Thus in English Broad Romic we write the diphthongs in *high* and *how* with the same vowel as *ask* (hai, hau, aask), although all these (a)'s represent different sounds in ordinary southern English pronunciation. But the pronunciation of these diphthongs varies so much in different parts of the English-speaking territory, and the distinctions are so minute that it would be inconvenient to express them in writing; and as these distinctions are non-significant, it would be useless to do so. (ai) and (au) are symbols, not of special diphthongs, but of two classes of diphthongs: they can stand for any diphthongs which begin with a vowel resembling the Italian *a*, and end with approximations to *i* and *u* respectively. Theoretically it would be just as correct in English and German to write these diphthongs (ae, ao). But these notations are misleading, because they suggest simple sounds.

In comparing the sounds of a variety of languages, or of dialects of a language, and still more in dealing with sounds in general, we require a "narrow," that is a minutely accurate, notation covering the whole field of possible sounds. It is evident from what has been said above that such a universal scientific alphabet is not suited for practical work in any one language. But the symbols of such a notation as Sweet's "Narrow Romic" are of the greatest use as keys to the exact pronunciation of the vaguer symbols of the Broad Romic notations of each language.

To prevent confusion between these two systems of notations Broad Romic symbols are enclosed in ( ), Narrow Romic in [ ], which at the same time serve to distinguish between phonetic and nomic spellings. This in English *i* (i) = [*i*] means that the English vowel in *finny* is the "wide" sound, not the "narrow" one in French *fini*, although in the Broad Romic notations of both languages (fini) is written for *finny* and *fini* alike.

Narrow Romic was originally based on A. J. Ellis's "Palaeotype," in which, as the name implies, no new letters are employed. The symbols of Palaeotype are made up, as far as possible, of the letters generally accessible in printing-offices, the ordinary Roman lower-case letters being supplemented by italics and small capitals (i, *i*, ɪ) and turned letters (ə, ɔ), many digraphs (th, sh) being also used. This notation was a reaction from Ellis's earlier phonotopy, in which a large number of new letters were used. Some of these, however, such as ʃ = (sh), ʒ = (zh), were afterwards adopted into Broad and Narrow Romic. In his Palaeotype Ellis also discarded diacritical letters, which, as he rightly says, are from a typographical point of view equivalent to new letters. In Narrow Romic a certain number of diacritical letters are used, such as (ñ, ä), most of which are already accessible. Palaeotype is a Roman-value notation, the main difference as regards the values of the symbols between it and the later systems being that it is more complex and arbitrary. Ellis afterwards had the unhappy idea of constructing a "Universal Glossic" on an English-values basis, which is even more cumbrous and difficult to remember than Palaeotype.

Sweet's Romic systems were made the basis of the "International" alphabet used in *Le Maître phonétique,* which is the organ of the International Phonetic Association, directed by P. Passy. Although this system is at the present time more widely known and used than any other, and although it is constructed on the international Romic principle, it is not really an international system. It is rather an attempt to make a special adaptation of the Romic basis to the needs of the French language into a general notation for all languages. But the phonetic structure of French is so abnormal, so different from that of other languages, that the attempt to force a Broad Romic French notation on such a language as English is even more hopeless than it would be to reverse the process. Although well suited for French, this alphabet must from a wider point of view be regarded as a failure: it is too minute and rigid for practical, and yet not precise enough for scientific purposes. In short, although it has done excellent service, and has helped to clear the way for a notation which shall command general acceptance, it cannot be regarded as a final solution of the problem.

Of the numerous other notations now in use, some still adhere to the diacritic principle of Lepsius's *Standard Alphabet* (1855), intended for missionary use, but found quite unfit for that purpose because of the enormous number of new types required. Most of them prefer to use new letters formed by more or less consistent modifications of the existing italic letters. A. J. Lundell's Swedish dialect alphabet and O. Jespersen's Danish dialect alphabet are good specimens of this tendency. In the latter Roman letters are used for special distinctions, just as italic letters are used in the Romic systems.

But in spite of all diversity, there is much agreement. As regards the vowels, the following approximate values are now pretty generally accepted :—

a	*as in*	father.	i	*as in*	it.
ai	,,	time.	o	,,	beau (Fr.).
au	,,	house.	œ	,,	peur (Fr.).
a·	,,	man.	ɔ	,,	fall.
e	,,	été (Fr.).	oi	,,	oil.
ei	,,	veil.	ou	,,	soul.
ɛ :	,,	there.	u	,,	full.
ə	,,	further.	y	,,	une (Fr.).

Vowel-length is in some systems denoted by doubling (aa), in others by special marks (a : &c.), the diacritic in *ā* being used only in the nomic orthographies of dead and oriental languages.

The only consonant-symbols that require special notice are the following :—

c	*as in*	tyúk (Hung.).	ŋ	*as in*	sing.
ç	,,	ich (German).	ʃ	,,	fish.
ð	,,	then.	þ	,,	thin.
j	,,	you.	w	,,	we.
ɟ	,,	nagy (Hung.).	x	,,	loch.
ɲ	,,	ogni (Ital.).	ʒ	,,	rouge.

All the systems of phonetic notation hitherto considered are based on the Roman alphabet. But although the Roman alphabet has many advantages from a practical point of view, it is evidently impossible to build up a consistent and systematic notation on such an inadequate foundation of arbitrary signs. What is wanted, for scientific purposes especially, is a notation independent of the Roman alphabet, built up systematically—an alphabet in which there is a definite relation between sound and symbol.

This relation may be regarded either from the organic or the acoustic point of view. The tendency of the earlier attempts at an a priori universal alphabet was to symbolize the consonants organically, the vowels acoustically, as in E. Brücke's *Phonetische Transscription* (1863). It is now generally acknowledged that the vowels as well as the consonants must be represented on a strictly organic basis. This was first done in A. M. Bell's *Visible Speech* (1867), which appeared again (1882) in a shorter form and with some modifications under the title of *Sounds and their Relations*. Bell's pupil, H. Sweet, gave a detailed criticism of Visible Speech in a paper on *Sound-notation* (Trans. of Philological Society, 1880–1881), in which he described a revised form of it called the *Organic Alphabet*, which he afterwards employed in his *Primer of Phonetics* and other works. Sweet's Narrow Romic notation already mentioned is practically a transcription of the Organic Alphabet into Roman letters.

Such notations are alphabetic: they go on the general principle of providing separate symbols for each simple sound. But as

the number of possible shades of sounds is almost infinite, even the most minutely accurate of them can do so only within certain limits. The Organic Alphabet especially makes a large use of "modifiers"—characters which are added to the other symbols to indicate nasal, palatal, &c., modifications of the sounds represented by the latter, these modifiers being generally represented by italic letters in the Narrow Romic transcription; thus (l*n*) = nasalized (l).

In the Roman alphabet such symbols as *f*, *v* are arbitrary, showing no connection in form either with one another or with the organic actions by which they are formed; but in the Organic symbol of *v*, for instance, we can see the graphic representation of its components "lips, teeth, voice-murmur." By omitting superfluous marks and utilizing various typographical devices the notation is so simplified that the symbols, in spite of their minute accuracy, are often simpler than in the corresponding Roman notation. The simplicity of the system is shown by the fact that it requires only about 110 types, as compared with the 280 of Lepsius's very imperfect Standard Alphabet.

All the systems hitherto considered are also alphabetic in a wider sense: they are intended for continuous writing, the more cumbrous "narrow" notations being, however, generally employed only in writing single words or short groups. An "analphabetic" basis was first definitely advocated by Jespersen, who represents each sound by a group of symbols resembling a chemical formula, each symbol representing not a sound, but an element of a sound: the part of the palate, tongue, &c., where the sound is formed, the degree of separation (openness) of the organs of speech, and so on. The two great advantages of such a system are that it allows perfect freedom in selecting and combining the elements and that it can be built up on the foundation of a small number of generally accessible signs.

As regards Jespersen's scheme, it is to be regretted that he has not worked it out in a more practical manner: that in his choice of the thirty odd symbols that he requires he should have gone out of his way to mix up Greek with Roman letters, together with other characters which would be avoided by any one constructing even a scientific alphabetic notation. And his use of these symbols is open to much criticism. In fact, it cannot be said that the analphabetic principle has yet had a fair trial.

The Organs of Speech.—Most speech-sounds are formed with air expelled from the lungs (voice-bellows), which passes through the two contractible bronchi or bronchial tubes into the also contractible wind-pipe or trachea, on the top of which is fixed the larynx (voice-box). Across the interior of the larynx are stretched two elastic ledges or cushions called "the vocal chords." They are inserted in front of the larynx at one end, and at the other they are fixed to two movable cartilaginous bodies "the aretynoids," so that the passage between them—the glottis—can be narrowed or closed at pleasure. The glottis is, as we see, twofold, consisting of the chord glottis and the cartilage glottis. The two can be narrowed or closed independently. The chords can also be tightened or relaxed, lengthened and shortened in various degrees.

When the whole glottis is wide open, no sound is produced by the outgoing breath except that caused by the friction of of the air. Sounds in whose formation the glottis is in this passive state are called "breath" sounds. Thus (f) is the breath consonant corresponding to the "voice" or "voiced" consonant (v). In the production of voice, the chords are brought close enough together to be set in vibration by the air passing between them. In the "thick" register of the voice (chest voice) the chords vibrate in their whole length, in the "thin" register or falsetto only in part of their length. If the glottis is narrowed without vibration, "whisper" is the result. In the "weak whisper" there is narrowing the whole glottis; in the "strong whisper," which is the ordinary form, the chord glottis is entirely closed, so that the breath passes only through the cartilage glottis. In what is popularly called "whisper"—that is, speaking without voice—the breath sounds remain unchanged, while voiced sounds substitute whisper (in the phonetic sense) for voice. Thus in whispering such a word as *feel* the (f) remains unchanged, while the following vowel and consonant are formed with the glottis only half closed. Whispered sounds—both vowels and consonants—occur in ordinary loud speech in many languages. Thus the final consonants in such English words as *leaves*, *oblige* are whispered, except when followed without a pause by a voiced sound, as in *obliging*, where the (ʒ) is fully voiced.

Above the glottis—still within the larynx—comes the "upper" or "false" glottis, by which the passage can be narrowed. On the top of the larynx is fixed a leaf-like body, the "epiglottis," which in swallowing, and sometimes in speech, is pressed down over the opening of the larynx. The contractible cavity between the larynx and the mouth is called the "pharynx." The roof of the mouth consists of two parts, the "soft" and the "hard palate." The lower pendulous extremity of the soft palate, the "uvula," in its passive state leaves the passage into the nose open. In the formation of non-nasal sounds, such as (b), the uvula is pressed up so as to close the passage from the pharynx into the nose. If (b) is formed with the passage open, it becomes the corresponding nasal consonant (m). The other extremity of the (hard) palate is bounded by the teeth, behind which are the gums, extending from the teeth-rim to the arch-rim—the projection of the teeth-roots or alveolars.

There is great diversity among phoneticians as regards the mapping out—the divisions—of the palate and tongue, and their names. Foreign phoneticians generally adopt very minute distinctions, to which they give Latin names. Bell in his *Visible Speech* makes a few broad fundamental divisions. In the arrangement adopted here (mainly based on his) sounds formed on the soft palate are called "back," and are subdivided into "inner" = nearer the throat, and "outer" = nearer the teeth, further subdivisions being made by the terms "innermost," "outermost," the position exactly half-way between these two last being defined as "intermediate back." Sounds formed on the hard palate or teeth may be included under the common term "forward," more accurately distinguished as "teeth" (dental), "gum," "front" (palatal, afterwards called "top" by Bell), which last is really equivalent to "mid-palatal," including the whole of the hard palate behind the gums. All of these divisions are further subdivided into "inner," &c., as with the back positions.

Of the tongue we distinguish the "back" (root), "front" or middle, "point" (tip), and "blade," which includes the point and the surface of the tongue immediately behind it. The tongue can also articulate against the lips, which, again, can articulate against the teeth. The lip passage can be closed, or narrowed in various degrees. Sounds modified by lip-narrowing are called "lip-modified" (labialized) or "round" (rounded), the last being specially used in speaking of vowels.

Speech-sounds.—The most general test of a simple as opposed to a compound sound (sound-group) is that it can be lengthened without change. As regards place of articulation, no sound is really simple: every sound is the result of the shape of the whole configurative passage from the lungs to the lips; and the ultimate sound-elements, such as voice, are never heard isolated. The most indistinct voice-murmur is as much the result of the shape of the superglottal passages as the clearest and most distinct of the other vowels; and its organic formation is as definite as theirs is, the only difference being that while in what we regard as unmodified voice all the organs except the vocal chords are in their passive, neutral positions, the other vowels are formed by actively modifying the shape of the superglottal passages—by raising the tongue towards the palate, narrowing the lips, &c.

The most important elements of speech-sounds are those which are dependent on the shape of the glottis and of the mouth passage respectively. It is on the relation between these two factors that one of the oldest distinctions between sounds is based: that of *vowel* and *consonant*. In vowels the element of voice is the predominant one: a vowel is voice modified by the different shapes of the superglottal passages. In consonants, on the other hand, the state of the glottis is only secondary.

Consonants are generally the result of audible friction, as in (f), or of complete stoppage, as in (p). If the glottis is at the same time left open, as in (f, p), the consonant is "breath" or "voiceless"—if it is narrowed enough to make the chords vibrate, as in (v, b), the consonant is "voice" or "voiced"; intermediate positions producing the corresponding "whispered" consonants. Vowels are characterized negatively by the absence of audible friction or stoppage: if an (i) is formed with the tongue so close to the palate as to cause buzzing, it becomes a variety of the front consonant (j). There is, of course no difficulty in forming a vowel with the glottis in the position for breat hand whisper. Thus breath (i) may often be heard in French in such words as *ainsi* at the end of a sentence, the result being practically a weak form of the front-breath consonant (ç). The division between vowel and consonant is not an absolutely definite one. As we see, the closer a vowel is—that is, the narrower its configurative passage is—the more like it is to a consonant, and the more natural it is to devocalize it. Some voice consonants, on the other hand, have so little buzz that acoustically they constitute a class between consonants and vowels—a class of "vowel-like" or "liquid" consonants, such as (n, m, l).

The changes in sounds which result from active narrowing of the passages admit of an important distinction as "sound-modifying" and "sound-colouring," although the distinction is not always definite. Nasality and rounding are examples of sound-modifying processes. Thus we hear a certain resemblance between (b) and (m), (i) and (y), but we regard all these four as distinct and practically independent sounds. Contraction of the pharynx, on the other hand, as also of the false glottis and windpipe, have only a sound-colouring effect: if a vowel is formed with such contractions its quality (timbre) is altered, but it still remains the same vowel. It follows from the definition of speech-sounds that they admit of a twofold classification: (1) organic and (2) acoustic. As already remarked, the older phoneticians used to classify the consonants organically, the vowels mainly from the acoustic point of view. The first to give an adequate organic classification of the vowels was the author of *Visible Speech*. Bell gave at the same time an independent acoustic classification of the consonants as well as the vowels. His acoustic classification consists simply in arranging the sounds in the order of their "pitches" (tone-heights). The pitches of the breath consonants are absolutely fixed in each individual pronunciation, while those of spoken vowels can be varied indefinitely within the compass of each voice by tightening the vocal chords in various ways and shortening their vibrating portions: the tighter and shorter the vibrating body, the quicker its vibrations, and the higher the tone. But when a vowel is whispered or breathed nothing is heard but the resonance of the configurative passages, especially in the mouth, and the pitches of these resonant cavities are as fixed as those of the breath consonants; in other words, a whispered (or breathed) vowel cannot be sung. Although the absolute pitches of voiceless sounds may vary from individual to individual the *relations* of the pitches are constant: thus in all pronunciations (ç) and whispered (i) are the highest, breath (w) in *what* and whispered (u) nearly the lowest in pitch among consonants and vowels respectively.

If phonetics were an ideally perfect science there would be no occasion to discuss whether the acoustic or the organic study of the vowels and the other speech-sounds is the more important: a full description of each sound would necessarily imply (1) an exact determination of its organic formation, (2) an acoustic analysis of the sound itself, both from the objective physical point of view and from the subjective one of the impression received by the ear, and (3) an explanation of how (2) is the necessary result of (1). Even this last question has already been solved to some extent. In fact, the connexion between the organic formation and the acoustic effect is often self-evident. It is evident, for instance, that (i) and (ç) owe their clear sound and high pitch to their being formed by short, narrow passages in the front of the mouth, while (u) owes its low pitch to being formed in exactly the opposite way, the sound being farther muffled and the pitch consequently still more lowered by the rounding.

One reason why it is impossible to classify the vowels exclusively on acoustic principles is that two vowels formed in quite different ways may have the same pitch. Thus the "high-front-round" (y) and the "high-mixed" (ï) have the same pitch, the tongue-retraction of the mixed position of the latter having the same effect as the rounding of the former. It is evident, therefore, that the fundamental classification of the vowels must, like that of the consonants, be purely organic. And although for practical purposes it is often convenient to classify sounds partly from the acoustic point of view, a full scientific treatment must keep the two points of view strictly apart, and make a special chapter of the relations between them.

Vowels.—The most obvious distinction between vowels is that which depends on the share of the lips in their articulation. In such non-round vowels as (i) and (a) the lips are passive, or even separated and spread out at their corners, by which the vowels assume a clearer resonance. If, on the other hand, the lips are actively approximated, they become the round vowels (y) and "open" (o) respectively.

Vowels are formed with different degrees of rounding. As a general rule, the narrowness of the lip-passage corresponds to the narrowness of the mouth-passage. Thus, in passing from the vowel of *too* to those of *no* and *saw* the back of the tongue is progressively lowered, and the rounding is diminished in the same proportion.

But there is also abnormal rounding. Thus, if we pronounce (o) with the lips in the position they have in forming (u), the resulting "over-rounded" vowel sounds half-way between (o) and (u); the second element of the diphthong (ou) in *go* is formed in this way. Conversely, the (u) in *put* is "under-rounded" in the North of England: the tongue position is kept, but the lips are only brought together a little at the corners, as in (ɔ).

The mouth positions of the vowels are the result of two factors: (1) the height of the tongue—its nearness to the palate—and (2) the degree of its retraction. Bell distinguishes three degrees of height: in his system (u) is "high," the (o) of *boy* is "mid," and the (ɔ) of *saw* is "low." He also has three degrees of retraction: in "back" vowels, such as (u), the root of the tongue is drawn to the back of the mouth, and the whole tongue slopes down from back to front. In "front" vowels, such as (i), the front of the tongue is raised towards the hard palate, so that the tongue slopes down from front to back.

Most of these slope-positions yield vowels of a distinct and clear resonance. There is also a class of "flat" vowels, such as (ə), in which the tongue is in a more or less neutral position. If the tongue is raised from the low-flat position of (əə) in *bird* to the high position, we get the (ï) of North Welsh *dyn* "man," which, as already observed, is acoustically similar to (y).

The flat vowels were called "mixed" by Bell, in accordance with his view that they are the result of combining back and front articulation. And although this view is now generally abandoned, the term "mixed" is still retained by the English school of phoneticians.

In this way Bell mapped out the whole mouth by the following cardinal points:—

high-back	high-mixed	high-front
mid-back	mid-mixed	mid-front
low-back	low-mixed	low-front

In this arrangement "high-back," &c., are fixed points like those of latitude and longitude. Thus normal "high" means that the tongue is raised as close to the palate as is possible without causing consonantal friction, and "back" implies retraction of the same kind. Intermediate positions are defined as "raised," "lowered," "inner," "outer."

The most original and at the same time the most disputed part of Bell's vowel-scheme is his distinction of "primary" and "wide." All vowels fall under one of these categories. Thus, the primary French (i) and the corresponding English wide (*i*) are both high-front-vowels, and yet they are distinct in sound: the English vowel is a semitone lower in pitch. Bell explained the greater openness of the wide vowels as the result of greater expansion of the pharynx; and he considered the other class to be most nearly allied to the consonants—whence their name "primary"—the voice-passages in the formation of primary vowels being expanded only so far as to remove all fricative quality. But alterations in the shape of the pharynx have only a sound-colouring, not a sound-modifying, effect; and Sweet showed that the distinction depends on the shape of the tongue, and accordingly substituted "narrow" for Bell's "primary." He also showed that the distinction applies to consonants as well as vowels: thus the narrow French (w) in *oui* is a consonantization of the narrow French (u) in *sou*, while the English (w) preserves the wide quality of the (*u*) in *put*.

In forming narrow sounds there is a feeling of tension in that

part of the tongue where the sound is formed, the tongue being clenched or bunched up lengthwise, so as to be more convex than in its relaxed or "wide" condition.

The distinction between narrow and wide can often be ignored in practical phonetic writing, for it generally depends on quantity; length and narrowness, shortness and wideness going together. When the distinction is marked, wide vowels may be expressed by italics, as in German (b*u*nə, b*i*n).

Bell's category of "mixed-round" vowels had from the beginning been a source of difficulty to students of *Visible Speech*. But it was not till 1901 that Sweet showed that they are only mixed as regards position: they are really the corresponding back-round vowels moved forward into the middle of the mouth while preserving the slope of back vowels, instead of having the tongue flat as in the (unround) mixed vowels. They are "out-back" vowels: there is an exaggeration of the outer back position of such a back-round vowel as the English (*u*) compared with the full back (*u*) in German *mutter*.

In the same way by moving the tongue backwards while forming a front vowel another series of "in-front" vowels is obtained.

The "in-mixed" vowels are obtained by shifting the neutral mixed positions into the full back position, keeping the tongue flat, so that these vowels might also be called "back-flat."

The out back, in-front and in-mixed vowels are included under the common designation of "shifted," as opposed to "normal" vowels.

There is a large number of other vowel-schemes, of which a survey will be found in W. Vietor's *Elemente der Phonetik*. Many of the older ones are in the form of triangles, with the three chief vowels *a*, *i*, *u* at the three corners, the other vowels being inserted between these extremes according to their acoustic relations. Since the appearance of *Visible Speech* many attempts have been made to fit his new vowels into these older schemes.

Of all the vowel-schemes the one now most generally known is perhaps that of the International Phonetic Association already mentioned. In this scheme the distinction of narrow and wide, though admitted and occasionally marked, is not an integral part of the system, the vowels being classified first as "velar" (back) and "palatal" (front), and then according to openness as "close," "half-close," "medium," "half-open" and "open."

Consonants.—These are the result of audible friction or stoppage, which may be accompanied either with breath, voice or whisper.

Consonants admit of a two-fold division (1) by form, and (2) by place. Thus (p, b) are by place lip-consonants, while by form they are stopped consonants or "stops."

If the mouth-stoppage is kept, and the nose-passage is opened, the stop becomes the corresponding "nasal"; thus (b) with the soft palate lowered becomes the nasal (m).

In "open" consonants the sound is formed by simply narrowing the passage, as in the back-open-breath (x) in Scotch and German *loch*. In some open consonants, such as the lip-teeth (f), there is slight contact of the organs, but without impeding the flow of breath.

In "divided" consonants there is central stoppage with openings at the sides, as in the familiar point-divided (l). These consonants are sometimes "unilateral"—with the opening on the side only—the character of the sound not being sensibly modified thereby.

When open and divided consonants are formed with the nose-passage open they are said to be "nazalized." Thus (m) with incomplete lip-closure becomes the nasalized lip-open-voice consonant.

"Trills" (or rolled) consonants are a special variety of un-stopped consonants resulting from the vibration of flexible parts against one another, as when the lips are trilled, or against some firm surface, as when the point of the tongue trills against the gums in the Scotch (r), or the uvula against the back of the tongue, as in the Northumbrian burred (r), and the French and German (r), where—especially in German—the trill is often reduced to a minimum or suppressed altogether.

As regards the place of consonants, there is, as already remarked, great diversity among phoneticians, both in mapping out the palate and tongue and in the names given to these divisions. The classification and nomenclature given here is, in the main, that of Bell.

By place, then, we distinguish seven main classes of consonants: back, front, point, blade, fan, lip, and lip-teeth.

"Back" (guttural) consonants are formed between the root of the tongue and the soft palate. In most languages the positions of these consonants vary according to those of the accompanying vowels: thus the back-stop and back-nasal in *king* are more forward than in *conquer*.

"Front" (palatal) consonants are formed between the middle of the tongue and the hard palate, the point of the tongue lying passively behind the lower teeth. It is easy to make the front-open-voice (j) in *you* into the corresponding stop (ɟ) by narrowing the passage till there is complete closure, as in Hungarian *nagy* (ɲɔɟ) "world." In the same way the open breath (ç) in German *ich* may be made into the stop (c) = Hungarian *ty*. (ɟ) nasalized becomes (ñ)—Italian *gn*, Spanish ñ, French *gn* in *vigne*. The front-divided-voice consonant is the Italian *gl* and Spanish *ll*. These are all simple sounds, distinct from the (lj), (nj) in French and English *million* and English *onion*.

"Point" consonants when formed against the teeth are called "point-teeth" (dental). English (þ) in *thin* is the point-teeth-open-breath consonant, (ð) in *then* the corresponding voice consonant. If (ð) is modified by turning the tip of the tongue back into the inner position—about on the arch-rim—it becomes the untrilled (r) in English *rearing*, in which position the tongue is easily trilled, the trilling becoming more and more difficult the more the tongue is approximated to the point-teeth position. In French and many other languages all the point consonants (t, d, n, l), &c., are formed on the teeth, except (r), which is always more retracted than the other point consonants. If the tip of the tongue is turned so far back as to articulate with its lower edge against the arch of the palate—that is, farther back than for the "inner" position—it is said to be "inverted." Inverted (r) is frequent in the dialects of the south-west of England. The opposite of inversion is "protrusion," in which the tip of the tongue articulates against the upper lip.

"Blade" consonants are formed by the blade or flattened tip of the tongue against the gums, as in English (s, z), or against the teeth, as in the corresponding French sounds. If these consonants are modified by turning the tongue a little back, so as to bring the point more into play, they become the "blade-point" consonants (ʃ, ʒ), as in *fish*, *measure*. (ʃ) is acoustically a dull (s). In some languages, such as German, sounds similar to (ʃ) and (z) are formed partly by rounding, which lowers the pitch of the hiss in the same way as retraction does, so that the tongue-articulation is only imperfectly carried out. When the rounding is very marked there is only a slight raising of the front of the tongue, as in some Swedish dialects; and if the tongue-articulation is progressively shifted back, and the rounding diminished in the same proportion, (ʃ) can at last develop into the pure back-open consonant (x), as in the present pronunciation of Spanish *x* and *j*.

The English point consonants (t, d, n, l) are formed on the gums just behind the teeth, the point of the tongue being flattened, so that they are almost blade consonants.

"Fan" (spread) consonants—the "emphatic" consonants of Arabic—are modifications of point and blade consonants, in which the sides of the tongue are spread out, so that the hiss of such a consonant as (s) is formed partly between the sides of the tongue and the back teeth, which gives a peculiar deep, dull quality to these sounds.

"Lip" consonants, such as (p, m), and "lip-teeth" consonants, such as (f, v), offer no difficulty. The simple lip-open-breath consonant does not occur in English; it is the sound produced in blowing out a candle. The corresponding voice sound is frequent in German—especially in Middle Germany—in such words as *quelle*.

If the lip-open consonants are modified by raising the back of the tongue, they become the "lip-back" consonants (wh, w) in English *what*, *we*, which may also be regarded as consonantized (*u*). In them the lip articulation predominates. In the "back-lip" consonants, as in German *auch*, the reverse is the case.

This last is one of a large number of "lip-modified" consonants, of which the already-mentioned German *sch* is a further example.

In a similar way consonants may be "front-modified." (l) is peculiarly susceptible to such modifications. In French and other languages it is formed with the tongue more convex than in English, and consequently with a tendency to front-modification. Front-modified (s) and point (r) may be heard in Russian in such words as *gusi* "goose," *tsari* "emperor," where the final vowels are silent.

Some consonants are formed below the mouth.

When the glottis is sharply opened or closed on a passage of breath or voice an effect is produced similar to that of a stop in the mouth, such as (k). This "glottal stop" is the sound produced in hiccuping; and is an independent sound in some languages, such as Arabic, where it is called "hamza." In German all words beginning with a stressed (accented) vowel have a more or less distinct glottal stop before the vowel.

Of the passages below the glottis, the bronchials and the wind-pipe are both susceptible of contraction.

Spasmodic contraction of the bronchial passages is the main factor in producing what is known as "the asthmatic wheeze." If this contraction is regulated and made voluntary it results in the deep hiss of the Arabic *ḥā*. If this sound is voiced, it causes a peculiar intermittent vibration of voice, which is habitual with some speakers, especially in Germany. If this effect is softened by slightly expanding the bronchial passages, an (r)-like sound is produced, which is that of the Arabic *'ain*.

Contraction of the windpipe produces a sound similar to the Arabic *ḥā*, but weaker, which when followed by a vowel has the effect of a strong aspirate. When voiced it becomes a mere colourer of the accompanying voice-murmur, or vowel, to which it imparts a deep timbre.

Non-expiratory Sounds.—All the sounds hitherto described imply out-breathing or expiration. Many of them can also be formed with in-breathing or inspiration. In English it is a not uncommon trick of speech to pronounce *no* in this manner, to express emphatic denial.

Some consonants are formed without either in- or out-breathing, but solely with the air in the throat or mouth. In forming "suction-stops" or "clicks" the tongue or lips are put in the position for a stop, and the air is sucked out from between the organs in contact, so that when the stop is loosened, a smacking sound is produced by the air rushing in to fill the vacuum. Thus the point-click is the interjection of impatience commonly written *tut!* In many savage languages clicks are a part of ordinary speech.

Synthesis.—Besides analysing each sound separately, phonetics has to deal with the phenomena which accompany synthesis or the combination of sounds. Although a sentence may consist of a single word, and that word of a single vowel, sounds mostly occur only in combination with one another. The ordinary division into sentences and words is logical, not phonetic: we cannot mark off sentences and cut them up into words until we know what they mean and are able to analyse them grammatically. But the logical division into sentences corresponds to some extent with the phonetic division into "breath-groups," marked off by our inability to utter more than a certain number of syllables in succession without pausing to take breath. Within each of these breath-groups there is no necessary pause between the words, except when we pause for emphasis. The only necessary phonetic divisions within the breath-group are those into syllables, sounds and intervening "glides." But before considering these last it will be necessary to say something about the general factors of synthesis: quantity, stress and intonation.

As regards *quantity*, it is enough for ordinary purposes to distinguish three degrees: long, half-long or medium, and short. In English what are called long vowels keep their full length when stressed and before final voice consonants, as in *see, broad*; and become half-long before voiceless consonants, as in *cease, brought*. In most other languages full length is preserved alike before all classes of consonants. The Romance languages have short final stressed vowels, as in French *si*. Unstressed vowels tend to become short in most languages. The distinctions of quantity apply to consonants as well as vowels. Thus English tends to lengthen final consonants after short stressed vowels, as in *man* compared with German *mann*, where the final consonant is quite short. Consonants, like vowels, tend to become short when unstressed. But in some languages, such as Finnish and Hungarian, stress has no effect on quantity, so that in these languages long vowels and double consonants occur as frequently in unstressed as in stressed syllables. Even in English we often lengthen final unstressed vowels in exclamations, as in *what a pity!* Some languages, such as the Romance languages and Russian, tend to level the distinctions of vowel-quantity: most of their vowels are half-long.

Stress is, organically, the result of the force with which the breath is expelled from the lungs; while acoustically it produces the effect of loudness, which is dependent on the size of the sound-vibrations: the bigger the waves, the louder the sound, and the greater the stress, of which we may distinguish infinite degrees. If we distinguish only three, they are called *weak, medium* and *strong*. The use of stress in different languages shows the same variety as quantity. Some languages, such as French, make comparatively little use of its distinctions, uttering all the syllables of words and sentences with a more or less even degree of force. English, on the other hand, makes great use of minute distinctions of stress both to distinguish the meanings of words and to mark their relations in sentences.

With stress is closely connected the question of *syllable-division*. A syllable is a group of sounds containing a "syllabic" or syllable-former, which is, of course, able to constitute a syllable by itself. The distinction between syllabics and non-syllabics depends on sonority, the more sonorous sounds being the voiced ones, while of these again, the most open are the most sonorous, the most sonorous of all being the vowels, among which, again, the openest are the most sonorous. But these differences are only relative. When a vowel and a consonant come together the sonorousness of the vowel always overpowers that of the consonant, so that the two together only constitute one syllable. But in such a word as *little* the second (l) is so much more sonorous than the accompanying voiceless stop that it assumes syllabic function, and the whole group becomes dissyllabic to the ear. The beginning of a syllable corresponds with the beginning of the stress-impulse with which it is uttered. Thus in *atone* the strong stress and the second syllable begin on the (t), and in *bookcase* on the second (k), the first (k) belonging to the first syllable, so that the (kk) is here double, not merely long, as in *book* (bukk) by itself.

Intonation or variation of tone (pitch) depends on the rapidity of the sound-vibrations: the more rapid the vibrations, the higher the pitch. Intonation is heard only in voiced sounds, as being the only ones capable of variations of pitch.

In singing the voice generally dwells on each note without change of pitch, and then leaps up or down to the next note as quickly as possible, so that the intervening "glide" is not noticed—except in what is called portamento. In speaking, on the other hand, the voice hardly ever dwells on any one note, but is constantly gliding upwards or downwards, so that an absolutely level tone hardly ever occurs in speech. But in the rising and falling inflections of speech we can distinguish between "voice-glides" (portamentos or slurs) and "voice-leaps," although the distinction is not so definite as in singing.

Of the three primary forms of intonation the level tone (-) can be approximately heard in *well* as an expression of musing—although it really ends with a slight rise; the rising(´) in the question *well?*; the falling (`) in the answer *yes*. There are besides compound tones formed by uniting the two last in one syllable. The compound rising tone (v) may be heard in *take care!* the compound falling tone (^) in the sarcastic *oh!* All these tones may be varied according to the intervals through which they pass. The greater the interval, the more emphatic the tone. Thus a high rise, which begins high, and consequently can only rise a little higher, expresses simple question, while the same word, if uttered with a low rise extending over an interval of between a fifth and an octave—or even more—expresses various degrees of surprise or indignation, as in the emphatic *what!* compared with the simply interrogative *what?*

In English and most European languages, intonation serves to modify the general meaning and character of sentences. This is *sentence-intonation*. But some languages, such as Swedish and Norwegian, and Chinese, have *word-intonation*, by which words which would otherwise be identical in sound are distinguished. The distinction between Gr. *oîkoi* and *oíkoi* was no doubt one of intonation.

Glides.—Such a word as *cat* consists not only of the vowel and the two consonants of which it is made up, but also of "glides" or transitions between these sounds. The glide from the initial consonant to the vowel consists of all the intermediate positions through which the tongue passes on its way from the (k)-position to the (ae)-position. The number of these positions is infinite, but they are all implied by the mere juxtaposition of the symbols, for it is assumed that in all transitions from one position to another the shortest way is taken. Although the direction of a glide is dependent on the positions of the two fixed points between which it lies, its character may be varied both by the shape of the configurative passages—especially the glottis—and by stress and quantity.

In the word given above the "off-glides" from the consonants are both breath-glides, the glottis being kept open during the transition from the voiceless consonant to the following vowel, or, as in the case of the final consonant, to silence. The "on-glide" from the vowel to the (t) is, on the other hand, a voice-glide, the closure of the glottis being maintained till the stop is made.

In French and most of the languages of the south of Europe voiceless consonants are followed by voice-glides. Thus in French *qui* there is no escape of breath after the (k), as there is in English *Key*. Other languages again have breath on-glides before voiceless stops.

If an independent strong stress is put on the breath-glide of English *key*, it is heard almost as a full independent consonant, and becomes an "aspirate." Aspirated steps may be heard in the Irish-English pronunciation of such words as *tell*, and also in Danish, and in Sanskrit as pronounced in India. If the voice-glide after a voice stop is emphasized in a similar way the "sonant aspirates" of Sanskrit and its modern descendants are produced, as in Sanskrit *dhanu*.

Glides are especially important from an acoustic point of view. Acoustically speaking, indeed, voiceless stops are pure glide-sounds, the stop itself being inaudible. In voice-stops, on the other hand, the stop itself can be made audible as well as the intervening glides. In English these latter are fully voiced when they come between voice sounds, as in *ago*; but when preceded by voiceless sounds or by a pause, as in *go!* they are formed with imperfect vocality, full voice being heard only just before the stop is loosened. So also initial English (z) as in *zeal* is formed with imperfect vocality under the same conditions, so that it sounds like (sz). In French and other languages which have voice-glides after voiceless consonants initial (g, z) &c. are fully voiced.

Consonant-glides may be further modified in various ways. In the formation of "implosive" stops, such as occur in Saxon German, Armenian and other languages, voiceless stops followed

by voice-glides are modified by simultaneous closure of the glottis, the larynx being raised by means of its muscles, so that it acts like a plug, compressing the air between the closed glottis and the mouth-stop, so that when the latter is released a peculiar choky effect is given to the off-glide.

Rounded glides may be heard in Russian in such words as *komnata*, where the rounding of the (o) is anticipated in the preceding consonant, being heard, of course, only in the off-glide of the consonant. The acoustic effect is between that of (kwo) and ordinary (ko).

Glideless consonant-combinations remain to be considered. The general articulative principle of taking the shortest way between sounds in juxtaposition necessarily results in certain transitions being effected without any glide at all. This is regularly the case when the consonants have the same place, and differ only in form, as in (nd, dlt), where the point of the tongue remains unmoved through the whole sound-group. In such combinations as (mf) the very slight glide is often got rid of entirely by assimilating the place of the first consonant to that of the second, so that the (m) becomes a lip-teeth consonant, as in English *nymph*.

Even when consonants are formed in different parts of the mouth it is often possible to join them without any glide. In English such combinations as (kt, pt) are glideless, the point of the tongue being brought into position before the preceding stop is loosened. In French and most other languages such consonants are separated by a breath-glide.

Combinations of stops and vowel-like consonants (tr, gl, kw) are glideless in English and most other languages. In English the breath-glide after a voiceless stop unvoices the beginning of the following vowel-like consonant; thus *try* is almost (trh-rai).

Vowel-glides.—Vowels are begun and ended in various ways. In the "gradual beginning," which is the usual one in English and French, the glottis is gradually narrowed while breath is being emitted. In the "clear" beginning the breath is kept back till the glottis is closed for voice, which begins without any "breathiness." German favours the clear beginning, generally exaggerating it into a glottal stop.

In the gradual as well as the clear beginning the stress begins on the vowel. If in the former it is thrown back on to the breath-glide, the latter is felt as an independent element and becomes the "aspirate" or (h), which in English and most other languages is a glide not only in the throat but in the mouth as well, the tongue and lips gradually moving up into the position for the following vowel while the glottis is being closed.

There is also a "strong" aspirate, which occurs in Finnish and other languages, in the formation of which the full vowel position is assumed from the beginning of the aspiration, which is therefore a voiceless vowel.

In most languages, when an aspirate comes between voiced sounds it is formed with imperfect vocality, the contrast of which with the full vocality of the other sounds is enough to produce the effect of breath. Thus in English *behold* the voice runs on without any actual break, the glottal closure being simply relaxed, not fully opened for breath, as in the emphatic *aha!* In some languages, such as Bohemian, this "voice-aspirate" is used everywhere, initially as well as medially.

Vowels are finished analogously, either by a gradual opening of the glottis, or by a cessation of aspiration while the glottis is still closed for voice. If stress is put on the gradual ending it becomes a distinct aspirate, as in the Sanskrit "visarga" in such a word as *manaḥ*.

Organic Basis.—Every language has certain general tendencies which control the formation of its sounds, constituting its "organic basis" or basis of articulation. The tendency of the present English is to flatten and lower the tongue and draw it back from the teeth, while the lips are kept as much as possible in a neutral position. The flattening of the tongue makes our vowels wide and favours the development of mixed vowels, and gives the dull quality which is especially noticeable in our (l); and its retraction is unfavourable to the development of teeth sounds; while the neutrality of the lips eliminates front-round vowels. In such a language as French everything is reversed. The tongue is arched, and raised, and advanced, and the lips articulate with energy. Hence French sounds tend to narrowness, dentality and distinct rounding.

National Sound-systems.—Each language uses only a part of the general phonetic material. Each one has only a limited number of sounds; and each one makes only a limited use of the synthetic distinctions of quantity, stress and intonation. As we have seen, many of these differences between individual languages are the result of, or may be referred to, differences in their organic basis.

Just as cognate languages differ from each other in phonetic structure, so also dialects of the same languages differ from each other more or less. Thus the sound-system of Lowland Scotch—which is, historically, a dialect of Northern English—differs considerably from that of standard English. Standard English itself was originally that mixture of the Midland and the Southern dialect which was spoken in London in the middle ages, just as standard French is, historically, the dialect of that district of which Paris is the centre. Standard English, like standard French, is now more a class-dialect than a local dialect: it is the language of the educated all over Great Britain. But it is not yet perfectly uniform. It is still liable to be influenced by the local dialects in grammar and vocabulary, and still more in pronunciation.

Again, English, like all other living languages, changes from generation to generation. Pronunciations which are vulgar in one century may become fashionable in the next. Sounds which are distinct in one generation may be confounded in another, and new distinctions may be made, new sounds may arise. A spoken language is, therefore, necessarily a vague and floating entity, and English is no exception to the rule. The very fixity of its written form gives all the freer play to the influences which cause change.

A standard spoken language is, strictly speaking, an abstraction. No two speakers of standard English pronounce exactly alike. And yet they all have something in common in every sound they utter. There are some divergencies, some peculiarities of pronunciation, which pass unnoticed, while others, less considerable perhaps in themselves, are at once felt as archaisms, vulgarisms or provincialisms, as the case may be, by the majority of educated speakers.

Sounds of English.—The following is a convenient classification of the vowels of standard English :—

a	ə	i	e	æ	u	o
aa	əə	ii	ei	uu	ou,	ɔ
ai, au					oi	
		iə	eə	uə		

Here the vowels are in four rows: (1) normally short, or, more correctly, monophthongic, (2) long, or half-diphthongic, (3) full diphthongs, (4) murmur-diphthongs.

Those under (1) are often lengthened in monosyllables such as *ten*, *good*, but they always remain absolutely monophthongic. The only one in the next row that is always strictly monophthongic is (əə): all the others, as we shall see, tend to become more or less diphthongic, especially in the south of England, being often exaggerated into full diphthongs of the (ai) and (au)-type in vulgar speech.

(a), as in *come up*, is the short vowel corresponding to the (aa) in *calm*. (aa) is the mid-back-wide vowel, and (a) differs from it only in being narrow. Acoustically, (a) is a muffled or obscure (aa): and the same effect may be produced by advancing the tongue from the mid-back to the corresponding out-back position, preserving the wide articulation: this pronunciation of *u* is common in the south of England. Historically, these sounds are the result of unrounding an older (u).

(ə), as in *sofa*, is a mixed vowel, tending to wideness and mid position, which occurs only unstressed. (əə) in *turn*, *earth*, is low-mixed-narrow. It is the result of absorption of an older (r), weakened into (ə).

(æ), as in *man*, is low-front-wide, from older mid-back-wide.

(i) in *it* is high-front-wide. The long (ii) in *eat* is narrow in the north of England, while in the south it is wide (i) followed by (j).

(e) in *men* is generally mid-front-wide. (ei) in *mane* is the same vowel either narrow or wide, raised in its latter half towards (*i*).

(u) in *good* is high-back-wide-round. Narrow (uu) in *too* becomes (*uw*) in southern English.

(o) in *not* is low-back-wide-round. In (ou), as in *no*, the mid-back-round vowel, either narrow or wide, is over-rounded in its latter half. (ɔ), as in *all*, is low-back-narrow-round.

The full diphthongs (ai, au, oi), as in *eye*, *now*, *oil*, all end in lowered high vowels. Their first elements are only roughly indicated by the transcription, and vary in the mouths of different speakers. That of (ai) is generally the out-mid-back-wide, that of (au) the broader low-mixed-wide, that of (oi) the mid-back-wide-round.

The murmur-diphthongs (iə) as in *here*, (eə) as in *air*, (uə) as in

poor, all tend to broaden their first elements. That of (eə) is the low-front-narrow vowel. The other two begin with lowered forms of the wide (ɪ) and (*u*) respectively. In (uə) the lowering is often carried so far as to make *poor* almost, or completely, into pore (pɔə).

The following arrangement of the English consonants will show their organic relations to one another :—

j	r; þ, ð	s, z; ʃ, ʒ	wh, w; f, v
	l		
k, g	t, d		p, b
ŋ	n		m

The "aspirate" (h) may be regarded either as a throat-consonant or as a breath-glide.

Characteristic features of the English consonant-system are the large number of hisses and buzzes, the sharp distinction of breath and voice, and, negatively, the absence of the open-back consonants, and of the voiceless forms of the vowel-like consonants (l, r) and the nasals, most of which still existed in Old English.

PHONOGRAPH (Gr. φωνή, sound, γράφειν, to write), an instrument for imprinting the vibrations of sound on a moving surface of tinfoil or wax in such a form that the original sounds can be faithfully reproduced by suitable mechanism. Many attempts had been made by earlier experimenters to obtain tracings of the vibrations of bodies emitting sound, such as tuning-forks, membranes, and glass or metallic disks. In 1807 Thomas Young (*Lectures*, i. 191) described a method of recording the vibrations of a tuning-fork on the surface of a drum; his method was fully carried out by Wilhelm Wertheim in 1842 (*Recherches sur l'élasticité, 1er mém.*). Recording the vibrations of a membrane was first accomplished by Leon Scott in 1857 by the invention of the "phonautograph," which may be regarded as the precursor of the phonograph (*Comptes rendus*, 53, p. 108). This instrument consisted of a thin membrane to which a delicate lever was attached. The membrane was stretched over the narrow end of an irregularly-shaped funnel or drum, while the end of the lever or marker was brought against the surface of a cylinder covered with paper on which soot had been deposited from a flame of turpentine or camphor. The cylinder was fixed on a fine screw moving horizontally when the cylinder was rotated. The marker thus described a spiral line on the blackened surface. When sounds were transmitted to the membrane and the cylinder was rotated the oscillations of the marker were recorded. Thus tracings of vibrations were obtained. This instrument was much improved by Karl Rudolph König, of Paris, who also made with it many valuable observations (see *Nature*, Dec. 26, 1901, p. 184). The mechanism of the recording lever or marker was improved by William Henry Barlow, in 1874, in an instrument called by him the "logograph" (*Trans. Roy. Soc.*, 1874). The next step was König's invention of manometric flames by which the oscillations of a thin membrane under sound-pressures acted on a small reservoir of gas connected with a flame, and the oscillations were viewed in a rotating rectangular mirror, according to a method devised by Charles Wheatstone. Thus flame-pictures of the vibrations of sound were obtained (*Pogg. Ann.*, 1864, cxxii. 242, 660; see also *Quelques expériences d'acoustique*, Paris, 1882). Clarence Blake in 1876 employed the drum-head of the human ear as a logograph, and thus obtained tracings similar to those made by artificial membranes and disks (*Archiv. für Ophthalmol.*, 1876, v. 1). In the same year Sigmund Theodor Stein photographed the vibrations of tuning-forks, violin strings, &c. (*Pogg. Ann.*, 1876, p. 142). Thus from Thomas Young downwards successful efforts had been made to record graphically on moving surfaces the vibrations of sounds, but the sounds so recorded could not be reproduced. This was accomplished by T. A. Edison in 1876, the first patent being dated January 1877.

In the first phonograph a spiral groove was cut on a brass drum fixed on a horizontal screw, so that when the drum was rotated it moved from right to left, as in the phonautograph. The recorder consisted of a membrane of parchment or gold-beater's skin stretched over the end of a short brass cylinder about 2 in in diameter. In the centre of the membrane there was a stout steel needle having a chisel-shaped edge, and a stiff bit of steel spring was soldered to the needle near its point, while the other end of the spring was clamped to the edge of the brass cylinder over which the membrane was stretched. The recorder was then so placed beside the large cylinder that the sharp edge of the needle ran in the middle of the spiral groove when the cylinder was rotated. The cylinder was covered with a sheet of soft tinfoil. During rotation of the cylinder, and while the membrane was not vibrating, the sharp edge of the marker indented the tinfoil into the spiral groove; and when the membrane was caused to vibrate by sounds being thrown into the short cylinder by a funnel-shaped opening, the variations of pressure corresponding to each vibration caused the marker to make indentations on the tinfoil in the bottom of the groove. These indentations corresponded to the sound-waves. To reproduce the sounds the recorder was drawn away from the cylinder, and the cylinder was rotated backwards until the recorder was brought to the point at which it started. The cylinder was then rotated forwards so that the point of the recorder ran over the elevations and depressions in the bottom of the groove. These elevations and depressions, corresponding to the variations of pressure of each sound-wave, acted backwards on the membrane through the medium of the marker. The membrane was thus caused to move in the same way as it did when it was made to vibrate by the sound-waves falling upon it, and consequently movements of the same general character but of smaller amplitude were produced, and these reproduced sound-waves. Consequently the sound first given to the phonograph was reproduced with considerable accuracy. In 1878 Fleeming Jenkin and J. A. Ewing amplified the tracings made on this instrument by the sounds of vowels, and submitted the curves so obtained to harmonic analysis (*Trans. Roy. Soc. Edin.* xxviii. 745). The marks on the tinfoil were also examined by P. F. F. Grützner, Mayer, Graham Bell, A. M. Preece, and Lahr (see *The Telephone, the Microphone, and the Phonograph*, by Count du Moncel, London, 1884; also *The Speaking Telephone and Talking Phonograph*, by G. B. Prescott, New York, 1878).

The tinfoil phonograph, however, was an imperfect instrument, both as regards the medium on which the imprints were taken (tinfoil) and the general mechanism of the instrument. Many improvements were attempted. From 1877 to 1888 Edison was engaged in working out the details of the wax-cylinder phonograph. In 1885 A. G. Bell and S. Tainter patented the "graphophone," and in 1887, Emile Berliner, a German domiciled in America, patented the "gramophone," wherein the cylinder was coated with lampblack, and the friction between it and the stylus was made uniform for all vibrations. Incidentally it may be mentioned that Charles Cross deposited in 1877 a sealed packet with the Académie des Sciences, Paris, containing a suggestion for reproducing sound from a Scott phonautograph record. The improvements made by Edison consisted chiefly (1) in substituting for tinfoil cylinders or disks made of a waxy substance on which permanent records are taken; (2) in substituting a thin glass plate for the parchment membrane; (3) in improving the mechanical action of the marker; and (4) in driving the drum carrying the wax cylinder at a uniform and rapid speed by an electric motor placed below the instrument.

In the first place, permanent records can be taken on the wax, which is composed of stearin and paraffin. This material is brittle, but it readily takes the imprints made by the marker, which is now a tiny bit of sapphire. The marker, when used for recording, is shod with a chisel-shaped edge of sapphire; but the sapphire is rounded when the marker is used for reproducing the sound. The marker also, instead of being a stiff needle coming from the centre of the membrane or glass plate, is now a lever, weighted so as to keep it in contact with the surface of the wax. A single vibration of a pure tone consists of an increase of pressure followed by a diminution of pressure. When the disk of glass is submitted to an increase of pressure the action of the lever is such that, while

by voice-glides are modified by simultaneous closure of the glottis, the larynx being raised by means of its muscles, so that it acts like a plug, compressing the air between the closed glottis and the mouth-stop, so that when the latter is released a peculiar choky effect is given to the off-glide.

Rounded glides may be heard in Russian in such words as *komnata*, where the rounding of the (o) is anticipated in the preceding consonant, being heard, of course, only in the off-glide of the consonant. The acoustic effect is between that of (kwo) and ordinary (ko).

Glideless consonant-combinations remain to be considered. The general articulative principle of taking the shortest way between sounds in juxtaposition necessarily results in certain transitions being effected without any glide at all. This is regularly the case when the consonants have the same place, and differ only in form, as in (nd, dlt), where the point of the tongue remains unmoved through the whole sound-group. In such combinations as (mf) the very slight glide is often got rid of entirely by assimilating the place of the first consonant to that of the second, so that the (m) becomes a lip-teeth consonant, as in English *nymph*.

Even when consonants are formed in different parts of the mouth it is often possible to join them without any glide. In English such combinations as (kt, pt) are glideless, the point of the tongue being brought into position before the preceding stop is loosened. In French and most other languages such consonants are separated by a breath-glide.

Combinations of stops and vowel-like consonants (tr, gl, kw) are glideless in English and most other languages. In English the breath-glide after a voiceless stop unvoices the beginning of the following vowel-like consonant; thus *try* is almost (trhrai).

Vowel-glides.—Vowels are begun and ended in various ways. In the "gradual beginning," which is the usual one in English and French, the glottis is gradually narrowed while breath is being emitted. In the "clear" beginning the breath is kept back till the glottis is closed for voice, which begins without any "breathiness." German favours the clear beginning, generally exaggerating it into a glottal stop.

In the gradual as well as the clear beginning the stress begins on the vowel. If in the former it is thrown back on to the breath-glide, the latter is felt as an independent element and becomes the "aspirate" or (h), which in English and most other languages is a glide not only in the throat but in the mouth as well, the tongue and lips gradually moving up into the position for the following vowel while the glottis is being closed.

There is also a "strong" aspirate, which occurs in Finnish and other languages, in the formation of which the full vowel position is assumed from the beginning of the aspiration, which is therefore a voiceless vowel.

In most languages, when an aspirate comes between voiced sounds it is formed with imperfect vocality, the contrast of which with the full vocality of the other sounds is enough to produce the effect of breath. Thus in English *behold* the voice runs on without any actual break, the glottal closure being simply relaxed, not fully opened for breath, as in the emphatic *aha!* In some languages, such as Bohemian, this "voice-aspirate" is used everywhere, initially as well as medially.

Vowels are finished analogously, either by a gradual opening of the glottis, or by a cessation of aspiration while the glottis is still closed for voice. If stress is put on the gradual ending it becomes a distinct aspirate, as in the Sanskrit "visarga" in such a word as *manaḥ*.

Organic Basis.—Every language has certain general tendencies which control the formation of its sounds, constituting its "organic basis" or basis of articulation. The tendency of the present English is to flatten and lower the tongue and draw it back from the teeth, while the lips are kept as much as possible in a neutral position. The flattening of the tongue makes our vowels wide and favours the development of mixed vowels, and gives the dull quality which is especially noticeable in our (l); and its retraction is unfavourable to the development of teeth sounds; while the neutrality of the lips eliminates front-round vowels. In such a language as French everything is reversed. The tongue is arched, and raised, and advanced, and the lips articulate with energy. Hence French sounds tend to narrowness, dentality and distinct rounding.

National Sound-systems.—Each language uses only a part of the general phonetic material. Each one has only a limited number of sounds; and each one makes only a limited use of the synthetic distinctions of quantity, stress and intonation. As we have seen, many of these differences between individual languages are the result of, or may be referred to, differences in their organic basis.

Just as cognate languages differ from each other in phonetic structure, so also dialects of the same languages differ from each other more or less. Thus the sound-system of Lowland Scotch—which is, historically, a dialect of Northern English—differs considerably from that of standard English. Standard English itself was originally that mixture of the Midland and the Southern dialect which was spoken in London in the middle ages, just as standard French is, historically, the dialect of that district of which Paris is the centre. Standard English, like standard French, is now more a class-dialect than a local dialect: it is the language of the educated all over Great Britain. But it is not yet perfectly uniform. It is still liable to be influenced by the local dialects in grammar and vocabulary, and still more in pronunciation.

Again, English, like all other living languages, changes from generation to generation. Pronunciations which are vulgar in one century may become fashionable in the next. Sounds which are distinct in one generation may be confounded in another, and new distinctions may be made, new sounds may arise. A spoken language is, therefore, necessarily a vague and floating entity, and English is no exception to the rule. The very fixity of its written form gives all the freer play to the influences which cause change.

A standard spoken language is, strictly speaking, an abstraction. No two speakers of standard English pronounce exactly alike. And yet they all have something in common in every sound they utter. There are some divergencies, some peculiarities of pronunciation, which pass unnoticed, while others, less considerable perhaps in themselves, are at once felt as archaisms, vulgarisms or provincialisms, as the case may be, by the majority of educated speakers.

Sounds of English.—The following is a convenient classification of the vowels of standard English :—

a	ə	i	e	æ	u	o
aa	əə	ii	ei	uu	ou,	ɔ
ai, au					oi	
		iə	eə	uə		

Here the vowels are in four rows: (1) normally short, or, more correctly, monophthongic, (2) long, or half-diphthongic, (3) full diphthongs, (4) murmur-diphthongs.

Those under (1) are often lengthened in monosyllables such as *ten*, *good*, but they always remain absolutely monophthongic. The only one in the next row that is always strictly monophthongic is (əə): all the others, as we shall see, tend to become more or less diphthongic, especially in the south of England, being often exaggerated into full diphthongs of the (ai) and (au)-type in vulgar speech.

(a), as in *come up*, is the short vowel corresponding to the (aa) in *calm*. (aa) is the mid-back-wide vowel, and (a) differs from it only in being narrow. Acoustically, (a) is a muffled or obscure (aa): and the same effect may be produced by advancing the tongue from the mid-back to the corresponding out-back position, preserving the wide articulation: this pronunciation of *u* is common in the south of England. Historically, these sounds are the result of unrounding an older (u).

(ə), as in *sofa*, is a mixed vowel, tending to wideness and mid position, which occurs only unstressed. (əə) in *turn*, *earth*, is low-mixed-narrow. It is the result of absorption of an older (r), weakened into (ə).

(æ), as in *man*, is low-front-wide, from older mid-back-wide.

(i) in *it* is high-front-wide. The long (ii) in *eat* is narrow in the north of England, while in the south it is wide (i) followed by (j).

(e) in *men* is generally mid-front-wide. (ei) in *mane* is the same vowel either narrow or wide, raised in its latter half towards (*i*).

(u) in *good* is high-back-wide-round. Narrow (uu) in *too* becomes (*uw*) in southern English.

(o) in *not* is low-back-wide-round. In (ou), as in *no*, the mid-back-round vowel, either narrow or wide, is over-rounded in its latter half. (ɔ), as in *all*, is low-back-narrow-round.

The full diphthongs (ai, au, oi), as in *eye*, *now*, *oil*, all end in lowered high vowels. Their first elements are only roughly indicated by the transcription, and vary in the mouths of different speakers. That of (ai) is generally the out-mid-back-wide, that of (au) the broader low-mixed-wide, that of (oi) the mid-back-wide-round.

The murmur-diphthongs (iə) as in *here*, (eə) as in *air*, (uə) as in

column of compressed air is controlled by a delicately adjusted grid-valve consisting of a metal comb rigidly connected to the stylus bar, so that as the needle moves the metal comb moves with it, following the lines of vibration fixed on the record and opening or closing the slots in the valve seat. The column of compressed air to which the valve gives access thus receives series of minute pulsations identical with those which originally produced the sounds recorded. In connexion with the sound-box is the apparatus for supplying compressed air, consisting of a sixth-horse-power electric motor driving the compressor, an oil filter, a reservoir and a dust collector to keep the air absolutely free from foreign substances likely to interfere with the action of the valve.

The practical possibilities of the gramophone are being realized in many countries. Matrices of the records of well-known artists have been deposited at the British Museum and at the Grand Opéra in Paris. Austria established a public phonogram record office in 1903, in which are collected folk-songs and records of all kinds for enriching the department of ethnography. The same idea is being carried out in Germany

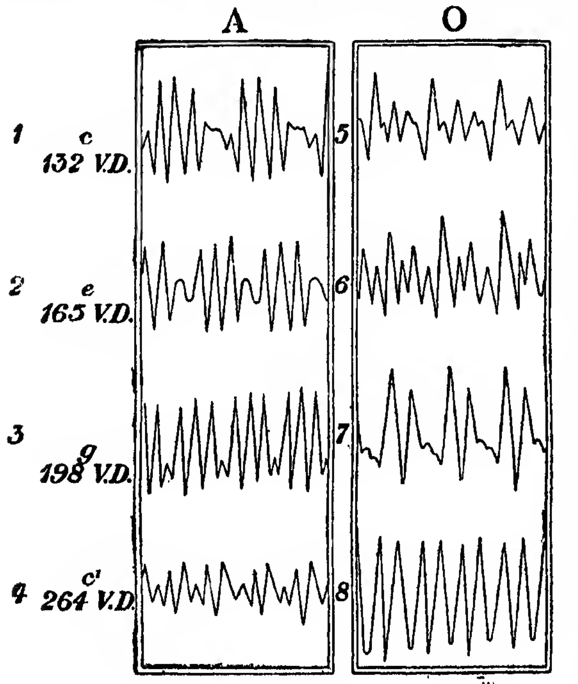

Fig. 2.

by private societies and by royal museums. In Hungary records of the various dialects have been secured. The possibilities of the gramophone as a teacher are far-reaching, not only in the domain of music but in learning languages, &c.

To understand how the phonograph records and reproduces musical tones, it is necessary to remember (1) that *pitch* or *frequency* depends on the number of vibrations executed by the vibrating body in a given period of time, or on the duration of each vibration; (2) that *intensity* or *loudness* depends on the amplitude of the movement of the vibrating body; and (3) that *quality, timbre* or *clang*, first, depends on the form of the individual vibrations, or rather on the power the ear possesses of appreciating a simple pendular vibration producing a pure tone, or of decomposing more or less completely a compound vibration into the simple pendular vibrations of which it is composed. If we apply this to the record of the phonograph, we find that, given a constant and sufficiently rapid velocity of the record, a note or tone of a certain pitch will be heard when the marker runs over a number of elevations and depressions corresponding to the frequency of that note. Thus if the note was produced by 200 vibrations per second, and suppose that it lasted in the music for $\frac{1}{10}$ of a second, 20 marks, each made in $\frac{1}{200}$ of a second, would be imprinted on the wax. Consequently, in reproduction, the marker would run over the 20 marks in $\frac{1}{10}$ of a second, and a tone of that frequency would be reproduced. The loudness would correspond to the depth of each individual mark on the cylinder or the width on the disk. The greater the depth of a series of successive marks produced by a loud tone, the greater, in reproduction, would be the amplitude of the excursions of the glass disk and the louder would be the tone reproduced. Lastly, the form of the marks corresponding to individual vibrations would determine the quality of the tone or note reproduced, by which we can distinguish the tone of one instrument from another, or the sensation produced by a tone of pure and simple quality, like that from a well-bowed tuning-fork or an open organ pipe, and that given by a trumpet or an orchestra, in which the sounds of many instruments are blended together. When the phonograph records the sound of an orchestra it does not record the tones of each instrument, but it imprints the form of impression corresponding to the very complex sound-wave formed by all the instruments combined. This particular form, infinitely varied, will reproduce backwards, as has been explained, by acting on the glass plate, the particular form of sound-wave corresponding to the sound of the orchestra. Numerous instruments blend their tones to make one wave-form, and when one instrument predominates, or if a human voice is singing to the accompaniment of the orchestra, another form of sound-wave, or rather a complex series of sound waves, is imprinted. When reproduced, the wave-forms again exist in the air as very complex variations of pressure; these act on the drum-head of the human ear, there is transmission to the brain, and there an analysis of the complex sensation takes place, and we distinguish the trombone from the oboe, or the human voice from the violin obbligato.

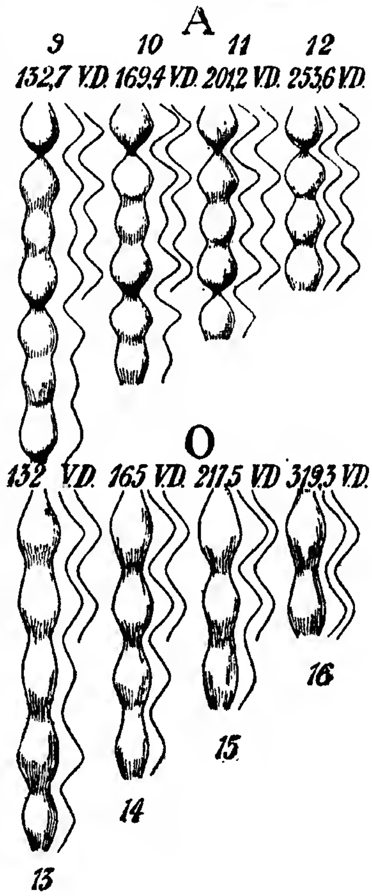

Fig. 3.

Many efforts have been made to obtain graphic tracings of wave-forms imprinted on the wax phonograph records. Thus J. G. M'Kendrick took (1) celloidin casts of the surface, and (2) microphotographs of a small portion of the cylinder (*Journ. of Anat. and Phys.*, July 1895). He also devised a phonograph recorder by which the curves were much amplified (*Trans. Roy. Soc. Edin.*, vol. xxxviii.; *Proc. Roy. Soc. Edin.*, 1896–1897, Opening Address; *Sound and Speech Waves as revealed by the Phonograph*, London, 1897; and *Schäfer's Physiol.*, vol. ii., "Vocal Sounds," p. 1229). As already mentioned, so long ago as 1878 Fleeming Jenkin and Ewing had examined the marks on the tinfoil phonograph. Professor Ludimar Hermann, of Königsberg, took up the subject about 1890, using the wax-cylinder phonograph. He obtained photographs of the curves on the wax cylinder, a beam of light reflected from a small mirror attached to the vibrating disk of the phonograph being allowed to fall on a sensitive plate while the phonograph was slowly travelling. (For references to Hermann's important papers, see *Schäfer's Physiology*, ii. 1222.) Boeke, of Alkmaar, has devised an ingenious and accurate method of obtaining curves from the wax cylinder. He measured by means of a microscope the transverse diameter of the impressions on the surface of the cylinder, on different (generally equidistant) parts of the period, and he infers

from these measurements the depth of the impressions on the same spot, or, in other words, he derives from these measurements the curve of the vibrations of the tone which produced the impression

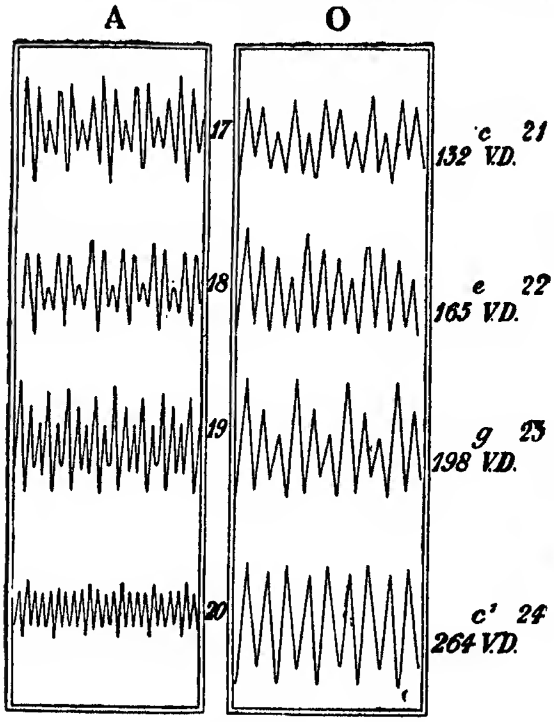

FIG. 4.

(*Archiv. f. d. ges. Physiol.*, Bonn, Bd. 1, S. 297; also *Proc. Roy. Soc. Edin.*, 1898).

From a communication to the Dutch Otorhinolaryngological Society Dr Boeke has permitted the author to select the accompanying illustrations, which will give the reader a fair conception of the nature of the marks on the wax cylinder produced by various tones. Fig. 2 shows portions of the curves obtained by Hermann, and enlarged by Boeke one and a half times. The numbers 1 to 4 refer to periods of the vowel A (as in "hard"), sung by Hermann on the notes *c e g c'*. Numbers 5 to 8 show the curves of the vowel O (as in "go") sung to the same notes. The number of vibrations is also noted. Boeke measured the marks for the same vowels by his method, from the same cylinder, and constructing the curves, found the relative lengths to be the same. In fig. 3 we see the indentations produced by the same vowels, sung by Hermann on the notes *c e g c'*, on the same phonograph cylinder, but delineated by Boeke after his method. The curves are also shown in linear fashion beside each group of indentations. From these measurements the curves were calculated and reproduced, as in fig. 4. Thus the curves of the same vowel sounds on the same cylinder are shown by two methods, that of Hermann and that of Boeke.

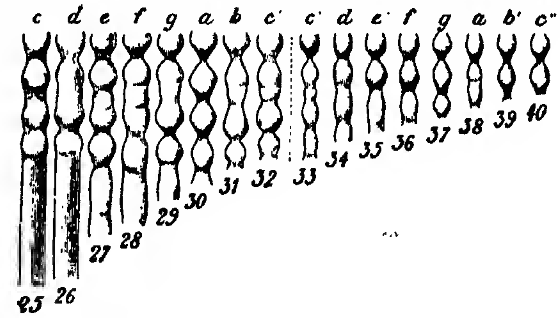

FIG. 5.

In fig. 5 we see the indentations on the vowel *a*, sung by Dr Boeke, aged 55, on the notes *c d e f g a b c'*, and near the frequencies of 128, 144, 160, 170·6, 192, 213·3, 240 and 256. The numbers 33 to 40 show the marks produced by the same vowel, sung by his son, aged 13. It will be seen that the boy sang the notes exactly an octave higher. Fig. 6 shows the marks produced by some musical

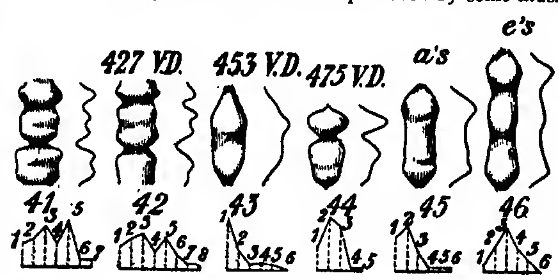

FIG. 6.

sounds. Each shows on the right-hand side the curve deduced from the marks, and under it a graphical representation of the results of its harmonic analysis after the theorem of Fourier, in which the ordinates represent the amplitude of the subsequent harmonic constituents. No. 41 is the period of the sound of a pitch-pipe giving *a'* (425 double vibrations per second), No. 42 the period of a Dutch pitch-pipe, also sounding *a'* (424·64 double vibrations per second). No. 43 is a record of the period of a sound produced by blowing between two strips of indiarubber to imitate the vocal cords, with a frequency of 453 double vibrations per second. No. 44 is that of a telephone pipe used by Hermann (503 double vibrations per second). Nos. 45 and 46 show the marks of a cornet sounding the notes *a* of ± 400 double vibrations per second, and *e* of 300 double vibrations per second. In fig. 7 are shown a number of vowel curves for the vowels O, OE, A, E and I. Each curve has on the right-hand side a graphical representation of its harmonic analysis. The curves are in five vertical columns, having on the

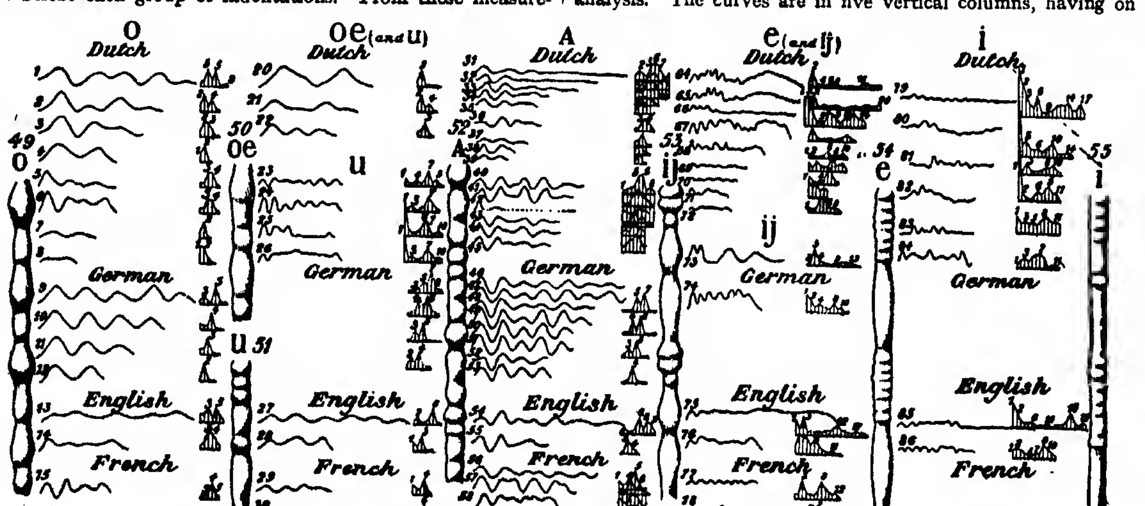

FIG. 7.

left-hand side of each drawings, by Boeke's method, of two periods of the marks of the vowel. The marks are shown for the Dutch, German, English and French languages. The sounds of the vowels are *o*, like *o* in "go"; *oe*, like *oo* in "too"; *u*, like the German *ü* in "Führer"; *a*, like *a* in "hard"; *e*, like *a* in "take"; *ij*, not in English words, but somewhat like *ē* in "bell"; and *i*, like *ee* in "beer." The first section contains only Dutch vowel sounds, either sung or spoken by Boeke or members of his family. The second section contains curves from the voice of Professor Hermann, the third from the voice of the author from a cylinder sent by him to Dr Boeke, and the fourth from the voice of Mons. H. Marichelle, professeur de l'Institut des Sourds-Muets, also forwarded by him to Dr Boeke. Thus curves and marks of the same vowel are shown from the voices of men of four nationalities.

On the construction of the gramophone, see L. N. Reddie, *Journ. Soc. Arts* (1908).

PHONOLITE (Gr. φωνή, sound, and λίθος, stone), in petrology, a group of volcanic lavas containing much nepheline and sanidine feldspar. The term "clinkstone" was formerly given by geologists to many fine grained compact lavas, which split into thin tough plates, and gave out a ringing sound when struck with the hammer. Some of these clinkstones were phonolites in the modern sense, but as the name clinkstone was used for a large variety of rocks, many of which have no close affinities with one another, it has been discarded and "phonolite" is substituted for it. The group includes rocks which are rich in alkalis with only a moderate percentage of silica; hence they contain no free quartz but much alkali feldspar (sanidine and anorthoclase) and nepheline. Large plates of sanidine are often visible in the rocks; the nepheline is usually not obvious to the unaided eye. Most phonolites show fluxion structure, both in the orientation of their phenocrysts and in the smaller crystals which make up the ground-mass; and this determines to a large extent the platy jointing. Although vitreous and pumiceous forms are known they are rare, and in the great majority of cases these rocks are finely crystalline with a dull or shimmering lustre in the ground-mass. Marked characteristics are the readiness with which they decompose, and the frequency of veins and cavities occupied by natrolite, analcite, scolecite and other zeolites. Small black grains of augite or hornblende and sometimes blue specks of haüyne may be seen in the rocks when they are fresh.

The dominant minerals are sanidine, nepheline, pyroxene, amphibole, various feldspathoids and iron oxides. The sanidine is usually in two generations, the first consisting of large crystals of flattened and tabular shape, while the second generation is represented by small rectangular prisms arranged in parallel streams in the ground-mass; these feldspars are nearly always simply twinned on the Carlsbad plan. They contain often as much soda as potash. The nepheline takes the form of hexagonal prisms with flat ends, and may be completely replaced by fibrous zeolites, so that it can only be recognized by the outlines of its pseudomorphs. In some phonolites it is exceedingly abundant in the ground-mass, and these rocks form transitions to the nephelinites (nephelinitoid phonolites) (see PETROLOGY, Plate III. fig. 1); in others it is scarce and the rocks resemble trachytes containing a little nepheline (trachytoid phonolites). The feldspathoid minerals, sodalite, haüyne and nosean, which crystallize in isometric dodecahedra, are very frequent components of the phonolites; their crystals are often corroded or partly dissolved and their outlines may then be very irregular. Small rounded enclosures of glass are often numerous in them. The pyroxenes may be pale green diopside, dark green aegirine-augite, or blackish green aegirine (soda iron pyroxene), and in many cases are complex, the outer portions being aegirine while the centre is diopside. Fine needles of aegirine are often found in the ground-mass. The commonest hornblende is dark brown barkevicite. Biotite and olivine are not really frequent in these rocks, and usually have been affected by resorption. The ordinary accessory minerals of igneous rocks, apatite, magnetite and zircon occur in the phonolites, and sphene is often rather common. Another mineral which is more frequent in phonolites than in many other rocks is brown melanite garnet.

The majority of the rocks of this group are of Tertiary or Recent age, but in Scotland Carboniferous phonolites occur in several localities, *e.g.* Traprain in Haddingtonshire, also in the Eildon Hills and in Renfrewshire. In Brazil phonolites belonging to the same epoch are also known. There are several districts in Europe where Tertiary or Recent phonolites occur in considerable numbers, as in Auvergne (Mont Dore), the Eifel, and Bohemia. The Wolf Rock which lies off the south coast of Cornwall, and is the site of a well-known lighthouse, is the only mass of phonolite in England; it is supposed to be the remains of a Tertiary lava or intrusion. The Canary Islands, Cape Verde Islands, Sardinia, Aden, British East Africa and New Zealand contain many types of phonolites; they are known also in New South Wales, while in the United States phonolites occur in Colorado (at Cripple Creek) and in the Black Hills of South Dakota.

Leucite occurs in place of nepheline in a small group of phonolites (the leucite-phonolites), known principally from Rocca Monfina and other places near Naples. Blue haüyne is rather a conspicuous mineral in some of these rocks, and they also contain a good deal of sphene. When sanidine, nepheline and leucite all occur together in a volcanic rock it is classed among the leucitophyres (see PETROLOGY, Plate III. fig. 2).

The chemical analyses of phonolites given below show that these rocks are very rich in alkalis and alumina with only a moderate amount of silica, while lime, magnesia and iron oxides are present only in small quantity. They have a close resemblance in these respects to the nepheline-syenites of which they provide the effusive types. (J. S. F.)

PHORCYS (PHORCUS, PHORCYN), in Greek mythology, son of Pontus (Sea) and Gaea (Earth), father of the Graeae, the Gorgons, Scylla, and Ladon (the dragon that guarded the golden apples of the Hesperides). In Homer (*Odyssey*, xiii. 96) he is an aged sea-deity, after whom a harbour in Ithaca was named. According to Varro (quoted by Servius in *Aeneid*, v. 824) Phorcys was a king of Corsica and Sardinia, who, having been defeated by King Atlas in a naval engagement in the course of which he was drowned, was subsequently worshipped as a marine divinity.

PHORMIUM, or NEW ZEALAND FLAX (also called "New Zealand hemp"), a fibre obtained from the leaves of *Phormium tenax* (nat. ord. Liliaceae), a native of New Zealand, the Chatham Islands and Norfolk Island. This useful plant is one of the many which were discovered by Sir Joseph Banks and Dr Solander who accompanied Captain Cook on his first voyage of discovery. The seeds brought home by Banks in 1771 did not succeed, but the plant was introduced by him to the Royal Gardens at Kew in 1789, and was thence liberally distributed in Great Britain and the continent of Europe. It grows luxuriantly in the south of Ireland, where it was introduced in 1798, and also flourishes on the west coast of Scotland, and is generally cultivated as an ornamental garden plant in Europe. It has been introduced for economic purposes into the Azores and California. The name Phormium is from Gr. φορμός, a basket, in allusion to one of the uses made of its leaves by the New Zealanders.

In its native country the plant is generally found near the coast. It has a fleshy rootstock, creeping beneath the surface of the soil and sending up luxuriant tufts of narrow, sword-shaped leaves, from 4 to 8 ft. long and from 2 to 4 in. in diameter. The leaves are vertical, and arranged in two rows as in the garden flag; they are very thick, stiff and leathery, dark green above, paler below, with the margin and nerve reddish-orange. From the centre of the tuft ultimately arises a tall flower-bearing stem, 5 to 15 ft. high, bearing on its numerous

branches a very large number of lurid red or yellow, somewhat tubular flowers, recalling those of an aloe, and from 1 to 2 in. long. After flowering the plant dies down, but increases by new lateral growths from the rootstock. The plant will grow in almost any soil, but best on light rich soil, by the side of rivers and brooks, where sheltered from the wind.

Phormium has been treated as a cultivated plant in New Zealand, though only to a limited extent; for the supplies of the raw material dependence has been principally placed on the abundance of the wild stocks and on sets planted as hedges and boundaries by the Maoris. Among these people the fibre has always been an article of considerable importance, yielding cloaks, mats, cordage, fishing-lines, &c., its valuable properties having attracted the attention of traders even before colonists settled in the islands. The leaves, for fibre-yielding purposes, come to maturity in about six months, and the habit of the Maoris is to cut them down twice a year, rejecting the outer and leaving the central immature leaves. Phormium is prepared with great care by native methods, only the mature fibres from the under-side of the leaves being taken. These are collected in water, scraped over the edge of a shell to free them from adhering cellular tissue and epidermis, and more than once washed in a running stream, followed by renewed scraping till the desired purity of fibre is attained. This native process is exceedingly wasteful, not more than one-fourth of the leaf-fibre being thereby utilized. But up till 1860 it was only native-prepared phormium that was known in the market, and it was on the material so carefully, but wastefully, selected that the reputation of the fibre was built up. The troubles with the Maoris at that period led the colonists to engage in the industry, and the sudden demand for all available fibres caused soon afterwards by the Civil War in America greatly stimulated their endeavours. Machinery was invented for disintegrating the leaves and freeing the fibre, and at the same time experiments were made with the view of obtaining it by water-retting, and by means of alkaline solutions and other chemical agencies. But the fibre produced by these rapid and economical means was very inferior in quality to the product of Maori handiwork, mainly because weak and undeveloped strands are, by machine preparation, unavoidably intermixed with the perfect fibres, which alone the Maoris select, and so the uniform quality and strength of the material are destroyed. The New Zealand government in 1893 offered a premium of £1750 for a machine which would treat the fibre satisfactorily, and a further £250 for a process of treating the tow; and with a view to creating further interest in the matter a member of a commission of inquiry visited England during 1897. The premium was again issued in 1899. In 1903 it was stated that a German chemist had discovered a method of working and spinning the New Zealand fibre. An idea of the extent of the growth of the fibre may be gathered from the fact that the exports for 1905 amounted to 28,877 bales at a value of nearly £700,000.

Phormium is a cream-coloured fibre with a fine silky gloss, capable of being spun and woven into many of the heavier textures for which flax is used, either alone or in combination with flax. It is, however, principally a cordage fibre, and in tensile strength it is second only to manila hemp; but it does not bear well the alternations of wet and dry to which ship-ropes are subject. The fibre has come into use as a suitable material for binder-twine as used in self-binding reaping machines.

PHORONIDEA, a zoological order, containing a single genus *Phoronis*, which is known to be of practically world-wide distribution, while there are many records of its larva, *Actinotrocha*, from localities where the adult has not been found. *Phoronis* is often gregarious, the tubes which it secretes being sometimes intertwined in an inextricable mass. These associations of individuals can hardly be the result of the metamorphosis of a corresponding number of larvae, but are probably due to a spontaneous fragmentation of the adult animals, each such fragment developing into a complete *Phoronis* (De Selys-Longchamps). The animal is from a quarter of an inch to six inches (*P. australis*) in length. The free end of the long vermiform body ends in a horseshoe-shaped "lophophore," or tentacle-bearing region (fig. 1, *a*), which strikingly resembles that of the Phylactolaematous Polyzoa (see POLYZOA).

In some species (figs. 2, 3) the two ends of the lophophore are rolled into spirals. An oral view of this region (fig. 2) shows: the mouth (*m*), continuous on either side with the groove between the two series of tentacles; the anus (*a*), in the middle line, at no great distance from the mouth; a transversely elongated epistome (*ep*), between the mouth and the anus; and, in the concavity of the lophophore, the apertures of the nephridia (*n.o.*) which, according to De Selys-Longchamps, open into the two large sensory or glandular "lophophoral organs" the orifices of which are seen at *gl*. The mouth leads into the oesophagus, which extends straight down the body nearly to the aboral end or "ampulla," where it dilates into a stomach, from which the ascending limb of the U-shaped alimentary canal passes directly to the anus. The coelomic body-cavity is divided by a transverse septum (fig. 3, *s*) which lies near the bases of the tentacles. The praeseptal or lophophoral coelom is continued into each of the tentacles and into the

body-wall. Each nephridium is provided with either one or two funnels which open into the postseptal division of the coelom (*ne.f*). The nervous system lies in the epidermis, externally to the basement-membrane. A general nerve-plexus probably exists over considerable parts of the skin, and there are special nervous concentrations in the region of the epistome and along a double crescent (*N*) which follows the parietal attachment of the coelomic septum. The part which lies at the base of the epistome is morphologically dorsal in position. It is said by Schultz (11) to develop, in specimens which are regenerating the lophophoral end, from an invagination of the ectoderm; and in this condition is compared by him with

the hollow central nervous system of some Enteropneusta and of Vertebrates. This comparison is not admitted by De Selys-Longchamps. The vascular system contains numerous red blood-corpuscles. The principal blood-channels are two longitudinal vessols which run down the entire length of the body, and are known as the "afferent" vessel (*af*) and the "efferent" vessel (*ef*) respectively, from their relation to the tentacles. According to researches in 1907 by De Selys-Longchamps, the blood is driven by the afferent vessel (*af*) to a crescentic lophophoral vessel (*d.v.*) which supplies the tentacles. Each of these contains a single blindly

ending vessel which bifurcates at its base (see fig. 3). One of these branches communicates with the afferent lophophoral vessel, while the other one opens into the crescentic efferent lophophoral vessel (*r.v.*). From this the blood passes into two lateral vessels which pierce the coelomic septum (*s.*), the right vessel proceeding on the anterior side of the oesophagus, as shown in fig. 3, to effect a union with the left one, and thus to constitute the main efferent vessel, which gives off numerous caecal branches as it passes down the body. Hence the blood returns once more to the afferent vessel through a splanchnic sinus which surrounds the stomach. The circulation is maintained by the rhythmical contraction of the afferent vessel and by less regular contractions of some of the other vessels. The reproductive organs lie on the left side, near the aboral end, both ovary and testis being present in the same individual in some of the species. They are said to be developed from the coelomic epithelium which covers the efferent vessel or its caeca. The reproductive cells pass to the exterior by means of the nephridia. Reproduction by budding does not occur, although spontaneous fragmentation of the body, followed by complete regeneration of each of the pieces, is known to take place. Regeneration of the tentacular end of the animal is of frequent occurrence.

Development and Affinities.—The eggs of *Phoronis* are small and usually undergo their early development attached to the tentacles of the adult. The attachment is probably effected (Masterman) by the secretion of the lophophoral organs (fig. 2, *gl.*). After the formation of an invaginate gastrula the larval form is rapidly acquired. On quitting the shelter of the parent tentacles the embryo becomes a pelagic larva, known as *Actinotrocha* (fig. 4) characterized by the possession of a line of tentacles running obliquely round the body. Locomotion is effected principally by means of a posterior ring of cilia surrounding the anus. The mouth (*o*) is in front of the tentacles, on the ventral side, and is overhung by a mobile praeoral hood, in which is the principal part of the nervous system. An oblique septum which follows the bases of the tentacles and corresponds with that of the adult animal divides the body-cavity into two portions. The postseptal division is a coelomic space, partially subdivided by a ventral mesentery. The praeseptal cavity is a vascular space, since it is in free communication with the dorsal vessel of the larva, and it persists in part as the two lophophoral vascular crescents of the adult. It contains two tufts of peculiar excretory cells, described by Goodrich (5) as "solenocytes," which surround the blind ends of a pair of nephridia. These pass backwards through the septum and open to the exterior ventrally. After the *Actinotrocha* has led a pelagic life for some time it develops a large ventral invagination of its body-wall (fig. 4, 2, iv.). At the metamorphosis, this sac is everted and the alimentary canal is drawn into it in the form of a loop (fig. 4, 3, 4). Most of the praetentacular region and the larval tentacles separate off, being then taken into the alimentary canal, where they are digested. The relations of the surfaces after the metamorphosis are clearly very different from those which obtained in the larva. The dorsal surface of the adult is the one between the mouth and the anus, while the median ventral line is the one which corresponds with the convexity of the alimentary canal. This view of the surfaces is, however, disputed by De Selys-Longchamps, who regards the aboral extremity of the adult as the posterior end.

The development of *Phoronis* was supposed by Caldwell (2) to furnish the explanation of the relations of the surfaces in Brachiopoda, Polyzoa and perhaps the Sipunculoid Gephyrea, in which the ontogenetic evidence is less clear. Caldwell's views were accepted by Lankester (8) in the 9th edition of this work, the Phylum Podaxonia being there instituted to include the groups just mentioned, together with the Pterobranchia. The peduncle of the Brachiopoda was supposed to correspond with the everted ventral sac of *Actinotrocha*, but the question is complicated by the want of any complete investigation of the development of the Brachiopoda, and by the absence of the anus in the majority of the genera. There is, however, a considerable amount of resemblance between the lophophore of *Phoronis australis*, with its spirally twisted ends, and that of a typical Brachiopod; nor do the structural details of the adult Brachiopods forbid the view that they may be related to *Phoronis*. The comparative study of the development does not support the hypothesis that the Polyzoa (*q.v.*) are comparable with *Phoronis*. In *Pedicellina*, the only Polyzoon in which the alimentary canal of the larva is known to become that of the first adult individual, the line between the mouth and anus is ventral in the larva; and since there is no reversal of the curvature of the digestive loop during the metamorphosis it must be regarded as ventral in the adult. There are, indeed, remarkable similarities between the external characters of the Phylactolaematous Polyzoa and the Phoronidea, and notably between their lophophores. The supposed occurrence of a pair of nephridia in certain Phylactolaemata, in a position corresponding with that of the nephridia of *Phoronis*, must also be mentioned,

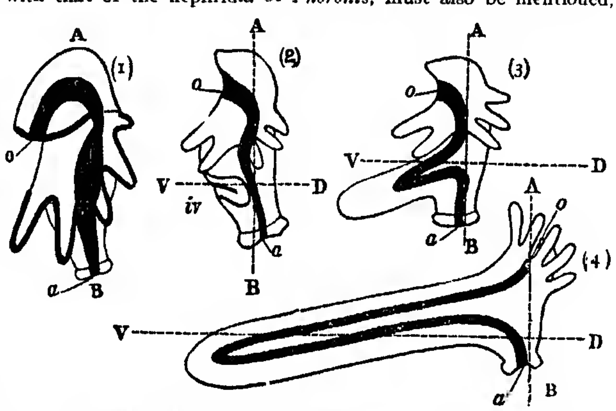

FIG. 4.—Diagrams illustrating the Metamorphosis of *Actinotrocha*.

although it has been maintained that the "nephridia" of Phylactolaemata are merely ciliated portions of the body-cavity and not indeed nephridia at all. But a serious objection to the comparison is that the development of Phylactolaemata can be explained by supposing it to be a modification of what occurs in other Polyzoa, while it appears to have no relation whatever to that of *Phoronis*.

Most observers consider that *Actinotrocha* is a highly modified Trochosphere, and this would give it some claim to be regarded as distantly related to the Entoproct Polyzoa and to other groups which have a Trochosphere larva.

Phoronis has long been regarded as a possible ally of *Rhabdopleura* (see PTEROBRANCHIA); and Masterman (10) has attempted to demonstrate the existence in *Actinotrocha* of most of the structures which occur in the Pterobranchia. According to his view the praeoral hood of *Actinotrocha* (cf. fig. 4) corresponds with the "proboscis" of Pterobranchia; the succeeding region, as far as the bases of the tentacles, with the collar; and the post-tentacular region with the metasome. Masterman's more detailed comparisons have for the most part been rejected by other morphologists. One of the most formidable difficulties in the way of the attempt to reduce *Actinotrocha* to the Pterobranchiate type of structure is the condition of the coelom in the former. There is indeed a perfectly definite transverse septum which divides the body-cavity in the region of the tentacle-bases. Even if it be admitted that the post-septal space may be the metasomatic cavity, the praeseptal space can hardly be regarded as coelomic in nature, since it is in continuity with the vascular system; while Masterman's conclusion that the cavity of the praeoral hood (the supposed proboscis-cavity) is separated from that of the supposed collar has received no confirmation. In spite of these difficulties it must be conceded that the dorsal flexure of the alimentary canal of the Pterobranchia is very *Phoronis*-like. It has, moreover, been shown (see especially Goodrich, 5) that shortly before its metamorphosis, *Actinotrocha* develops a coelomic space which lies immediately in front of the oblique septum, and gives rise later to the cavity of the lophophore and tentacles. Regarding this as a collar-cavity, it becomes possible to agree with Masterman that the region shown in fig. 4, 1, between the tentacles and the praeoral hood, is really a collar the coelom of which develops relatively late. It will be noticed that the lophophore of *Phoronis* is, on this assumption, a derivative of the collar just as it is in the Pterobranchia. The epistome of the adult *Phoronis* cannot well be the proboscis since its cavity is continuous with the lophophoral coelom, and because the praeoral hood of *Actinotrocha* is entirely lost at the metamorphosis. It is possible that this consideration will account for the want of an anterior body-cavity in *Phoronis*. Since the proboscis is a purely larval organ in this genus, it may be supposed that the coelomic space which properly belongs to it fails to develop, but that the praeoral hood itself is none the less the morphological representative of the proboscis. In spite of the criticisms which have been made on the conclusion that *Phoronis* is allied to the Pterobranchia, it is thus possible that the view is a sound one, and that the Phoronidea should take their place, with the Enteropneusta and the Pterobranchia, as an order of the Hemichordata.

PHORORHACOS, the best-known genus of the extinct Patagonian *Stereornithes* (see BIRD: *Fossil*). Among the bones found in the strata of the Santa Cruz formation (now considered as mainly of mid-Miocene date) was the piece of a mandible which F. Ameghino described in 1887 as that of an edentate mammal, under the name of *Pherysrhacos longissimus* (*Bolet. Mus. de la Plata*, i. 24). In 1891 (*Rev. Argent. Hist. Nat.* i. 225)

(From life-size model in Brit. Mus. Nat. Hist.)

Skull of Phororhacos, *longissimus*.

he amended the name and recognized the bone as that of a bird, *Phororhacos*, which with *Brontornis* and others constituted the family *Phororhacidae*. About six species of the type genus are now known, the most complete being *Ph. inflatus*, with skull, mandible, pelvis, limbs and some of the vertebrae. These birds were at first considered as either belonging to the Ratitae, or at least related to them, until C. W. Andrews, after much of the interesting material had been acquired by the British Museum, showed the gruiform affinities of *Phororhacos* (*Ibis*, 1896, pp. 1-12), a conclusion which he was able to further corroborate after the clearing of the adherent stony matrix from the skulls (*Tr. Z. S.* 1901, xv. pp. 55-86, pls. 14-17). The skull of *Ph. longissimus* is about 2 ft. long and 10 in. high; that of *Ph. inflatus* is 13 in. long, and this creature is supposed to have stood only 3 ft. high at the middle of the back. The under jaw is slightly curved upwards and it contains a large foramen as for instance in *Psophia* and in *Mycteria*. The strongly hooked upper beak is very high, and very much compressed laterally. The palate is imperfectly desmognathous, as in *Dicholophus*, with an inconspicuous vomer. The quadrate has a double knob for its articulation with the skull, and basipterygoid processes are absent. What little is known of the shoulder-girdle (breastbone still unknown) points to a flightless bird, and so do the short wing bones, although these are stout. The pelvis has an ischiadic foramen. The hind limbs are distinctly slender, the tibia of *Ph. inflatus* being between 15 and 16 in. in length.

For further detail see F. Ameghino, "Sur les oiseaux fossiles de la Patagonie," *Bolet. inst. geogr. argentino*, xv., chs. 11 and 12 (1895); F. P. Moreno and A. Mercerat, *Catálogo de los pájaros fósiles de la República Argentina, An. Mus. La Plata* (1891; with 21 plates). (H. F. G.)

PHOSGENITE, a rare mineral consisting of lead chlorocarbonate, $(PbCl)_2CO_3$. The tetragonal (holosymmetric) crystals are prismatic or tabular in habit, and are bounded by smooth, bright faces: they are usually colourless and transparent, and have a brilliant adamantine lustre. Sometimes the crystals have a curious helical twist about the tetrad or principal axis. The hardness is 3 and the specific gravity 6·3. The mineral is rather sectile, and consequently was early known as "corneous lead" (Ger. *Hornblei*). The fanciful name phosgenite was given by A. Breithaupt in 1820, from phosgene, the old name of carbon oxychloride, because the mineral contains the elements carbon, oxygen and chlorine. At Cromford, near Matlock, it was long ago found in an old lead mine, being associated with anglesite and matlockite (Pb_2OCl_2) in cavities in decomposed galena: hence its common name cronfortite. Fine crystals are also found in galena at Monteponi near Iglesias in Sardinia, but the largest are those recently found near Dundas in Tasmania. Crystals of phosgenite, and also of the corresponding bromine compound $[PbBr]_2CO_3$, have been prepared artificially.

(L. J. S.)

PHOSPHATES, in chemistry, the name given to salts of phosphoric acid. As stated under PHOSPHORUS, phosphoric oxide, P_2O_5, combines with water in three proportions to form $H_2O \cdot P_2O_5$ or HPO_3, metaphosphoric acid; $2H_2O \cdot P_2O_5$ or $H_4P_2O_7$, pyrophosphoric acid; and $3H_2O \cdot P_2O_5$ or H_3PO_4, orthophosphoric or ordinary phosphoric acid. These acids each give origin to several series of salts, those of ordinary phosphoric acid being the most important, and, in addition, are widely distributed in the mineral kingdom (see below, under *Mineral Phosphates*).

Orthophosphoric acid, H_3PO_4, a tribasic acid, is obtained by boiling a solution of the pentoxide in water; by oxidizing red phosphorus with nitric acid, or yellow phosphorus under the surface of water by bromine or iodine; and also by decomposing a mineral phosphate with sulphuric acid. It usually forms a thin syrup which on concentration in a vacuum over sulphuric acid deposits hard, transparent, rhombic prisms which melt at 41·7°. On long heating the syrup is partially converted into pyrophosphoric and metaphosphoric acids, but on adding water and boiling the ortho-acid is re-formed. It gives origin to three classes of salts: $M'H_2PO_4$ or $M''H_4P_2O_8$; M'_2HPO_4 or $M''HPO_4$, M'_3PO_4, $M''_3P_2O_8$ or $M'''PO_4$, wherein M',M'',M''' denote a mono-, di-, and tri-valent metal. The first set may be called monometallic, the second dimetallic, and the third trimetallic salts. Per-acid salts of the alkalis, *e.g.* $(K,Na,NH_4)H_5(PO_4)_2$, are also known; these may be regarded as composed of a monometallic phosphate

with phosphoric acid, thus $M'H_2PO_4 \cdot H_3PO_4$. The three principal groups differ remarkably in their behaviour towards indicators. The monometallic salts are strongly acid, the dimetallic are neutral or faintly alkaline, whilst the soluble trimetallic salts are strongly alkaline. The monometallic salts of the alkalis and alkaline earths may be obtained in crystal form, but those of the heavy metals are only stable when in solution. The soluble trimetallic salts are decomposed by carbonic acid into a dimetallic salt and an acid carbonate. All soluble orthophosphates give with silver nitrate a characteristic yellow precipitate of silver phosphate, Ag_3PO_4, soluble in ammonia and in nitric acid. Since the reaction with the acid salts is attended by liberation of nitric acid: $NaH_2PO_4 + 3AgNO_3 = Ag_3PO_4 + NaNO_3 + 2HNO_3$, $Na_2HPO_4 + 3AgNO_3 = Ag_3PO_4 + 2NaNO_3 + HNO_3$, it is necessary to neutralize the nitric acid if the complete precipitation of the phosphoric acid be desired. The three series also differ when heated: the trimetallic salts, containing fixed bases are unaltered, whilst the mono- and di-metallic salts yield meta- and pyro-phosphates respectively. If the heating be with charcoal, the trimetallic salts of the alkalis and alkaline earths are unaltered, whilst the mono- and di-salts give free phosphorus and a trimetallic salt. Other precipitants of phosphoric acid or its salts in solution are: ammonium molybdate in nitric acid, which gives on heating a canary-yellow precipitate of ammonium phosphomolybdate, $12[MoO_3](NH_4)_3PO_4$, insoluble in acids but readily soluble in ammonia; magnesium chloride, ammonium chloride and ammonia, which give on standing in a warm place a white crystalline precipitate of magnesium ammonium phosphate, $Mg(NH_4)PO_4 \cdot 6H_2O$, which is soluble in acids but highly insoluble in ammonia solutions, and on heating to redness gives magnesium pyrophosphate, $Mg_2P_2O_7$; uranic nitrate and ferric chloride, which give a yellowish-white precipitate, soluble in hydrochloric acid and ammonia, but insoluble in acetic acid; mercurous nitrate which gives a white precipitate, soluble in nitric acid, and bismuth nitrate which gives a white precipitate, insoluble in nitric acid.

Pyrophosphoric Acid, $H_4P_2O_7$, is a tetrabasic acid which may be regarded as derived by eliminating a molecule of water between two molecules of ordinary phosphoric acid; its constitution may therefore be written $(HO)_2OP \cdot O \cdot PO(OH)_2$. It may be obtained as a glassy mass, indistinguishable from metaphosphoric acid, by heating phosphoric acid to 215°. When boiled with water it forms the ortho-acid, and when heated to redness the meta-acid. After neutralization, it gives a white precipitate with silver nitrate. Being a tetrabasic acid it can form four classes of salts; for example, the four sodium salts $Na_4P_2O_7$, $Na_3HP_2O_7$, $Na_2H_2P_2O_7$, $NaH_3P_2O_7$ are known. The most important is the normal salt, $Na_4P_2O_7$, which is readily obtained by heating disodium orthophosphate, Na_2HPO_4. It forms monoclinic prisms (with $10H_2O$) which are permanent in air. All soluble pyrophosphates when boiled with water for a long time are converted into orthophosphates.

Metaphosphoric Acid, HPO_3, is a monobasic acid which may be regarded as derived from orthophosphoric acid by the abstraction of one molecule of water, thus $H_3PO_4 - H_2O = HPO_3$; its constitution is therefore $(HO)PO_2$. The acid is formed by dissolving phosphorus pentoxide in cold water, or by strongly heating orthophosphoric acid. It forms a colourless vitreous mass, hence its name "glacial phosphoric acid." It is readily soluble in water, the solution being gradually transformed into the ortho-acid, a reaction which proceeds much more rapidly on boiling. Although the acid is monobasic, salts of polymeric forms exist of the types $(MPO_3)_n$, where n may be 1, 2, 3, 4, 6. They may be obtained by heating a monometallic orthophosphate of a fixed base, or a dimetallic orthophosphate of one fixed and one volatile base, *e.g.* microcosmic salt: $MH_2PO_4 = MPO_3 + H_2O$, $(NH_4)NaHPO_4 = NaPO_3 + NH_3 + H_2O$; they may also be obtained by acting with phosphorus pentoxide on trimetallic orthophosphates: $Na_3PO_4 + P_2O_5 = 3NaPO_3$. The salts are usually non-crystalline and fusible. On boiling their solutions they yield orthophosphates, whilst those of the heavy metals on boiling with water give a trimetallic orthophosphate and orthophosphoric acid: $3AgPO_3 + 3H_2O = Ag_3PO_4 + 2H_3PO_4$. On heating with an oxide or carbonate they yield a trimetallic orthophosphate, carbon dioxide being evolved in the latter case. Metaphosphoric acid can be distinguished from the other two acids by its power of coagulating albumen, and by not being precipitated by magnesium and ammonium chlorides in the presence of ammonia.

(C. E.*)

Mineral Phosphates.—Those varieties of native calcium phosphate which are not distinctly crystallized, like apatite (*q.v.*), but occur in fibrous, compact or earthy masses, often nodular, and more or less impure, are included under the general term phosphorite. The name seems to have been given originally to the Spanish phosphorite, probably because it phosphoresced when heated. This mineral, known as Estremadura phosphate, occurs at Logrossan and Cáceres, where it forms an important deposit in clay-slate. It may contain from 55 to 62 % of calcium phosphate, with about 7 % of magnesium phosphate. A somewhat similar mineral, forming a fibrous incrustation, with a mammillary surface, and containing about 9 % of calcium carbonate, is known as staffelite, a name given by A. Stein in 1866 from the locality Staffel, in the valley of the Lower Lahn, where (as also in the valley of its tributary the Dill) large deposits of phosphorite occur. Dahllite is a Norwegian phosphorite, containing calcium carbonate, named in 1888 by W. C. Brögger and H. Bäckström after the Norwegian geologists T. and J. Dahll. Osteolite is a white earthy phosphorite occurring in the clefts of basaltic rocks, named in 1851 by J. C. Bromeis from the Greek ὀστέον, bone.

Phosphorite, when occurring in large deposits, is a mineral of much economic value for conversion into the superphosphate largely used as a fertilizing agent. Many of the impure substances thus utilized are not strictly phosphorite, but pass under such names as "rock-phosphate," or, when nodular, as "coprolite" (*q.v.*), even if not of true coprolitic origin. The ultimate source of these mineral phosphates may be referred in most cases to the apatite widely distributed in crystalline rocks. Being soluble in water containing carbonic acid or organic acids it may be readily removed in solution, and may thus furnish plants and animals with the phosphates required in their structures. On the decay of these structures the phosphates are returned to the inorganic world, thus completing the cycle.

There are three sources of phosphates which are of importance geologically. They occur (*a*) in crystalline igneous and metamorphic rocks as an original constituent, (*b*) in veins associated with igneous rocks, and (*c*) in sedimentary rocks either as organic fragments or in secondary concretionary forms.

The first mode of occurrence is of little significance practically, for the crystalline rocks generally contain too little phosphate to be valuable, though occasionally an igneous rock may contain enough apatite to form an inferior fertilizing agent, *e.g.* the trachyte of Cabo de Gata in south-east Spain, which contains 12–15 % of phosphoric acid. In many deposits of iron ores found in connexion with igneous or metamorphic rocks small quantities of phosphate occur. The Swedish, Norwegian, Ontario and Michigan mines yield ores of this kind; and though none of them can be profitably worked as a source of phosphate, yet on reducing the ore it may be retained in the slags, and thus rendered available for agriculture.

Another group of phosphatic deposits connected with igneous rocks comprises the apatite veins of south Norway, Ottawa and other districts in Canada. These are of pneumatolytic origin (see PNEUMATOLYSIS), and have been formed by the action of vapours emanating from cooling bodies of basic eruptive rock. Veins of this type occur at Oedegarden in Norway and Dundret in Lapland. From 1500 to 3500 tons of apatite are obtained yearly in Norway from these veins. In Ontario apatite has been worked for a long time in deposits of similar nature. The total output of Canada in 1907 was only 680 tons.

The phosphatic rocks which occur among the sedimentary strata are the principal sources of phosphates for commerce and agriculture. They are found in formations of all ages from the Cambrian to those which are accumulating at the present day. Of the latter the best known is guano (see MANURES and MANURING).

Where guano-beds are exposed to rain their soluble constituents are removed and the insoluble matters left behind. The soluble phosphates washed out of the guano may become fixed by entering into combination with the elements of the rock beneath. Many of the oceanic islets are composed of coral limestone, which in this

way becomes phosphatized; others are igneous, consisting of trachyte or basalt, and these rocks are also phosphatized on their surfaces but are not so valuable, inasmuch as the presence of iron or alumina in any quantity renders them unsuited for the preparation of artificial manures.

The leached guanos and phosphatized rocks, which are grouped with them for commercial purposes, have been obtained in great quantities in many islands of the Pacific Ocean (such as Baker, Howland, Jarvis and McKean Islands) between long. 150° to 180° W. and lat. 10° N. to 10° S. In the West Indies from Venezuela to the Bahamas and in the Caribbean Sea many islands yield supplies of leached guanos; the following are important in this respect: Sombrero, Navassa, Aves, Aruba, Curaçoa. Christmas Island has been a great source of phosphates of this type; also Jaluit Island in the Maldive Archipelago, Banaba or Ocean Island, and Nauru or Pleasant Island. On Christmas Island the phosphate has been quarried to depths of 100 ft. To these leached guanos and phosphatized limestones the name sombrerite has been given. It has been estimated that 500,000 tons of phosphate were obtained in Aruba, 1,000,000 tons from Curaçoa since the deposits were discovered in 1870, and Christmas Island in 1907 yielded 290,000 tons.

In the older formations the phosphates tend to become more and more mineralized by chemical processes. In whatever form they were originally deposited they often suffer complete or partial solution and are redeposited as concretionary lumps and nodules, often called coprolites. The "Challenger" and other oceanographic expeditions have shown that on the bottom of the deep sea concretions of phosphate are now gathering around the dead bodies of fishes lying in the oozes; consequently the formation of the concretions may have been carried on simultaneously with the deposition of the strata in which they occur.

Important deposits of mineral phosphates are now worked on a large scale in the United States, the annual yield far surpassing that of any other part of the world. The most active operations are carried on in Florida, where the phosphate was first worked in 1887 in the form of pebbles in the gravels of Peace River. Then followed the discovery of "hard rock-phosphate," a massive mineral, often having cavities lined with nearly pure phosphorite. Other kinds not distinctly hard and consisting of less rich phosphatic limestone, are known as "soft phosphate": those found as smooth pebbles of variable colour are called "land pebble-phosphate," whilst the pebbles of the river-beds and old river-valleys, usually of dark colour, are distinguished as "river pebble-phosphate." The land pebble is worked in central South Florida; the hard rock chiefly between Albion and Bay City. In South Carolina, where there are important deposits of phosphate, formerly more productive than at present, the "land rock" is worked near Charleston, and the "river rock" in the Coosaw River and other streams near Beaufort. The phosphate beds contain Eocene fossils derived from the underlying strata and many fragments of Pleistocene vertebrata such as mastodon, elephant, stag, horse, pig, &c. The phosphate occurs as lumps varying greatly in size, scattered through a sand or clay; they often contain phosphatized Eocene fossils (Mollusca, &c.). Sometimes the phosphate is found at the surface, but generally it is covered by alluvial sands and clays. Phosphate mining began in South Carolina in 1868, and for twenty years that state was the principal producer. Then the Florida deposits began to be worked. In 1892 the phosphates of Tennessee, derived from Ordovician limestones, came into the market. From North Carolina, Alabama and Pennsylvania, also, phosphates have been obtained but only in comparatively small quantities. In 1900 mining for phosphates was commenced in Arkansas. In 1908 Florida produced 1,673,651 tons of phosphate valued at 11 million dollars. All the other states together produce less phosphate than Florida, and among them Tennessee takes the first place with an output of 403,180 tons.

Algeria contains important deposits of phosphorite, especially near Tebessa and at Tocqueville in the province of Constantine. Near Jebel Kouif, on the frontier between Algeria and Tunis, there are phosphate workings, as also in Tunis, at Gafsa. The deposits belong to the Lower Eocene, where it rests unconformably upon the Cretaceous. The joint production of Tunis and Algeria in 1907 was not less than a million tons. Phosphates occur also in Egypt, in the desert east of Keneh and in the Dakla oasis in the Libyan desert.

France is rich in mineral phosphates, the chief deposits being in the departments of the Pas-de-Calais, Somme, Aisne, Oise and Meuse, in the north-east, and another group in the departments of Lot, Tarn-et-Garonne and Aveyron, in the south-west: phosphates occur also in the Pyrenees. The deposits near Caylus and in Quercy occupy fissures and pockets in Jurassic limestone, and have yielded a remarkable assemblage of the relics of Tertiary mammals and other fossils. Phosphates occur in Belgium, especially near Mons, and these, like those of north-east France, are principally in the Upper Chalk. Two varieties of phosphate rock are recognized in these districts, viz. the phosphatic chalk and the phosphate sand, the latter resulting from the decomposition of the former. Large and valuable deposits of the sand have been obtained in sinks and depressions on the surface of the chalk. The production is on the whole diminishing in Belgium (180,000 tons in 1907), but in France it is still large (375,000 tons in 1907).

In the Lahn district of Nassau (Germany) there are phosphate beds in Devonian rocks. The deposits were rich but irregular and local, and were much worked from 1866 to 1884, but are no longer of economic importance. In northern Estremadura in Spain and Alemtezo in Portugal there are vein deposits of phosphate of lime. As much as 200,000 tons of phosphate have been raised in these provinces, but in 1906 the total production of Spain was only 1300 tons. Large deposits of phosphate occur in Russia, and those in the neighbourhood of Kertch have attracted some attention; it is said that the Cretaceous rocks between the rivers Dniester and Volga contain very large supplies of phosphate, though probably of low grade.

Phosphatic nodules and concretions, with phosphatized fossils and their casts, occur at various geological horizons in Great Britain. Bands of black nodules, highly phosphatic, are found at the top of the Bala limestone in North Wales; beds of concretions occur in the Jurassic series; and important deposits are known in the Cretaceous strata, especially in the Lower Greensand and at the base of the Gault. The Lower Greensand phosphates have been worked, under the name of "coprolites," at Potton in Bedfordshire and at Upware and Wicken in Cambridgeshire. The Cambridge Greensand, rich in phosphatic nodules, occurs at the base of the Chalk Marl. The chalk occasionally becomes phosphatized, as at Taplow (Bucks) and Lewes (Sussex). At the base of the Red Crag in East Anglia, and occasionally at the base of the other Pliocene Crags, there is a "nodule bed," consisting of phosphatic nodules, with rolled teeth and bones, which were formerly worked as "coprolites" for the preparation of artificial manure. Professor R. J. Strutt has found that phosphatized nodules and bones are rich in radioactive constituents, and has brought this into relation with their geological age.

Bibliography.—For American phosphates see *The Phosphates of America*, by Francis Wyatt (5th ed., New York and London, 1894); the Annual Reports on *Mineral Resources of the U.S.* (U.S. Geol. Survey), including some valuable reports by C. W. Hayes, also those in Rothwell's *Mineral Industry*; "Nature and Origin of Deposits of Phosphate of Lime," by R. A. F. Penrose, jun., *Bull. U.S. Geol. Survey, No. 46* (1888); *Florida, South Carolina and Canadian Phosphates*, by C. C. Hoyer Millar (London, 1892); and *The Non-metallic Minerals*, by G. P. Merrill (1904). Many of the above include descriptions of mineral phosphates in other parts of the world. For a general discussion of the origin of the phosphates, see "The Natural History of Phosphate Deposits," by J. J. H. Teall, *Proc. Geol. Assoc.* (1900), xvi. 369. (J. S. F.; F. W. R.*)

PHOSPHORESCENCE, a name given to a variety of physical phenomena due to different causes, but all consisting in the emission of a pale, more or less ill-defined light, not obviously due to combustion. The word was first used by physicists to describe the property possessed by many substances of themselves becoming luminous after exposure to light. This property has been noticed from early times. Pliny speaks of various gems which shine with a light of their own, and Albertus Magnus knew that the diamond becomes phosphorescent when moderately heated. But the first discovery of this property which apparently attracted scientific attention seems to have been that of the Bologna stone (barium sulphide), which was discovered

by Vincenzo Cascariolo, a cobbler of Bologna, in about 1602. This was followed by the discovery of a number of other substances which become luminous either after exposure to light or on heating, or by attrition, and to which the general name of "phosphori" (from φῶς and φόρος, bringing light) was given. Among these may be mentioned Homberg's phosphorus (calcium chloride), John Canton's phosphorus (calcium sulphide) and Balduin's phosphorus (calcium nitrate). Of late years it has been found convenient to limit the strict meaning of the word "phosphorescence" to the case of bodies which, after exposure to light, become self-luminous (even if only for a fraction of a second). The general term "luminescence" has been proposed by E. Wiedemann to include all cases in which bodies give off light not due to ignition. This general term embraces several subdivisions. Thus, fluorescence (*q.v.*) and phosphorescence are included under the same heading, "photoluminescence," being distinguished from each other only by the fact that fluorescent bodies emit their characteristic light only while under the influence of the exciting illumination, while phosphorescent bodies are luminous for an appreciable time after the exciting light is cut off.

Phosphorescence, in its restricted meaning as above explained, is most strikingly exhibited by the artificial sulphides of calcium, strontium and barium. If any of these substances is exposed for some time to daylight, or, better, to direct sunlight, or to the light of the electric arc, it will shine for hours in the dark with a soft coloured light. The colour depends not only on the nature of the substance, but also on its physical condition, and on its temperature during insolation, that is, exposure to the sun's rays. Thus the phosphorescent light emitted by calcium sulphide may be orange-yellow, yellow, green or violet, according to the method of preparation and the materials used. Balmain's luminous paint, a preparation of calcium sulphide, shines with a white light. The colour also depends on the temperature during exposure to light. Thus A. E. Becquerel found that the light given by a specimen of strontium sulphide changed from violet to blue, green, yellow and orange, as the temperature during the corresponding previous insolation was 20°, 40°, 70°, 100° or 200° C. The duration of phosphorescence varies greatly with different substances. It may last for days or for only a fraction of a second.

As in the case of fluorescent bodies, the light produced by phosphorescent substances consists commonly of rays less refrangible than those of the exciting light. Thus the ultra-violet portion of the spectrum is usually the most efficient in exciting rays belonging to the visible part of the spectrum. V. Klatt and Ph. Lenard (*Wied. Ann.*, 1889, xxxviii. 90), have shown that the phosphorescence of calcium sulphide and other phosphori depends on the presence of minute quantities of other substances, such as copper, bismuth and manganese. The maximum intensity of phosphorescent light is obtained when a certain definite proportion of the impurity is present, and the intensity is diminished if this proportion is increased.

It appears likely that when a phosphorescent body is exposed to light, the energy of the light is stored up in some kind of strain energy, and that the phosphorescent light is given out during a more or less slow recovery from this state of strain. Klatt and Lenard have shown that the sulphides of the alkaline earths lose the property of phosphorescing when subjected to heavy pressure. Many fluorescent solutions become briefly phosphorescent when rendered solid by gelatin.

When the duration of phosphorescence is brief, some mechanical device becomes necessary to detect it. The earliest and best-known instrument for this purpose is Becquerel's phosphoroscope. It consists essentially of a shallow drum, in whose ends two eccentric holes, exactly opposite one another, are cut. Inside it are fixed two equal metal disks, attached perpendicularly to an axis, and divided into the same number of sectors, the alternate sectors of each being cut out. One of these disks is close to one end of the drum, the other to the opposite end, and the sectors are so arranged that, when the disks are made to rotate, the hole in one end is open while that in the other is closed, and vice versa. If the eye be placed near one hole, and a ray of sunlight be admitted by the other, it is obvious that while the sun shines on an object inside the drum the aperture next the eye is closed, and vice versa. If the disks be made to revolve with great velocity by means of a train of toothed wheels the object will be presented to the eye almost instantly after it has been exposed to sunlight, and these presentations succeed one another so rapidly as to produce a sense of continuous vision. By means of this apparatus we can test with considerable accuracy the duration of the phenomenon after the light has been cut off. For this purpose we require to know merely the number of sectors in the disks and the rate at which they are turned.

Thermoluminescence.—Some bodies which do not emit light at ordinary temperatures in a dark room begin to do so if they are heated to a temperature below a visible red heat. In the case of chlorophane, a variety of fluorspar, the heat of the hand is sufficient. Many yellow diamonds exhibit this form of luminescence. It has been shown, however, that a previous exposure to light is always necessary. Sir James Dewar found that if ammonium platino-cyanide, Balmain's paint and some other substances are cooled to the temperature of liquid air and exposed to light, they do not phosphoresce, but as soon as they are allowed to warm up to the ordinary temperature they emit a brilliant light. On the other hand, some bodies, such as gelatin, celluloid, paraffin and ivory, are phosphorescent at very low temperatures, but lose the property at ordinary temperatures.

Triboluminescence (from τρίβειν, to rub) is luminescence excited by friction, percussion, cleavage or such mechanical means. Calcium chloride, prepared at a red heat, exhibits this property. If sugar is broken in the dark, or two crystals of quartz rubbed together, or a piece of mica cleft, a flash of light is seen, but this is probably of electrical origin. Closely allied to this form of luminescence is *crystalloluminescence*, a phosphorescent light seen when some substances crystallize from solution or after fusion. This property is exhibited by arsenious acid when crystallizing from solution in hydrochloric acid.

Chemiluminescence is the name given to those cases in which chemical action produces light without any great rise of temperature. Phosphorus exposed to moist air in a dark room shines with a soft light due to slow oxidation. Decaying wood and other vegetable substances often exhibit the same property.

Electroluminescence is luminescence due to electrical causes. Many gases are phosphorescent for a short time after an electric discharge has been passed through them, and some solid substances, especially diamonds and rubies, are strongly phosphorescent when exposed to kathode rays in a vacuum tube.

See generally, Winkelmann, *Handbuch der Physik*, Bd. vi. (1906); E. Becquerel, *La Lumière* (1867). (J. R. C.)

Phosphorescence in Zoology.

The emission of light by living substance is a widespread occurrence, and is part of the general metabolism by which the potential energy introduced as food is transformed into kinetic energy and appears in the form of movement, heat, electricity and light. In many cases it is probably an accidental by-product, and like the heat radiated by living tissues, is not necessarily of use to the organism. But in other cases the capacity to produce light is awakened on stimulation, as when the wind ripples the surface of the sea, or when the water is disturbed by the blade of an oar. It has been suggested that the response to the stimulus may be protective, and that enemies are frightened by the flash of light. In luminous insects and deep-sea fish the power of emitting light appears to have a special significance, and very elaborate mechanisms have been developed. The pale glow of phosphorescence has a certain resemblance to the light emitted by phosphorus, and it was an early suggestion that the phenomenon in living organisms was due to that substance. Phosphorus, however, and its luminous compounds are deadly poisons to all living tissues, and never occur in them in the course of natural metabolism, and the phosphorescence of life cannot therefore be assigned to the oxidation of phosphorus. On the other hand, it is certainly the result of a process of oxidation, as the emission of light continues only in the presence of oxygen. J. H. Fabre showed in 1855 that the luminous fungus, *Agaricus*, discharges more carbonic acid when it is emitting light, and Max Schultze in 1865 showed that in insects the luminous cells are closely associated with the tracheae, and that during phosphorescence they withdraw oxygen from them. In 1880 B. Radziszewski showed that many fats, ethereal oils and alcohols emit light when slowly combined with oxygen in alkaline fluids at appropriate temperatures. Probably the phosphorescence of organisms is due to a similar process acting on the many fats, oils and similar substances found in living cells. The colour varies much in different organisms; green has been observed in the glow-worm, fire-flies, brittle-stars, centipedes and annelids; blue in the Italian fire-fly (*Luciola italica*); blue and light green are the predominant colours in the phosphorescence of marine organisms, but red and lilac have also been observed. The Lantern-Fly (*Fulgora pyrorhynchus*) is said to have a purple light, and E. H. Giglioli has recorded that an individual *Appendicularia* appeared first red, and then blue, and then green. P. Panceri, chiefly in the case of *Salps*, and S. P. Langley and F. W. Very in the case of *Pyrophorus*, have investigated the light spectroscopically, and

way becomes phosphatized; others are igneous, consisting of trachyte or basalt, and these rocks are also phosphatized on their surfaces but are not so valuable, inasmuch as the presence of iron or alumina in any quantity renders them unsuited for the preparation of artificial manures.

The leached guanos and phosphatized rocks, which are grouped with them for commercial purposes, have been obtained in great quantities in many islands of the Pacific Ocean (such as Baker, Howland, Jarvis and McKean Islands) between long. 150° to 180° W. and lat. 10° N. to 10° S. In the West Indies from Venezuela to the Bahamas and in the Caribbean Sea many islands yield supplies of leached guanos; the following are important in this respect: Sombrero, Navassa, Aves, Aruba, Curaçoa. Christmas Island has been a great source of phosphates of this type; also Jaluit Island in the Maldive Archipelago, Banaba or Ocean Island, and Nauru or Pleasant Island. On Christmas Island the phosphate has been quarried to depths of 100 ft. To these leached guanos and phosphatized limestones the name sombrerite has been given. It has been estimated that 500,000 tons of phosphate were obtained in Aruba, 1,000,000 tons from Curaçoa since the deposits were discovered in 1870, and Christmas Island in 1907 yielded 290,000 tons.

In the older formations the phosphates tend to become more and more mineralized by chemical processes. In whatever form they were originally deposited they often suffer complete or partial solution and are redeposited as concretionary lumps and nodules, often called coprolites. The "Challenger" and other oceanographic expeditions have shown that on the bottom of the deep sea concretions of phosphate are now gathering around the dead bodies of fishes lying in the oozes; consequently the formation of the concretions may have been carried on simultaneously with the deposition of the strata in which they occur.

Important deposits of mineral phosphates are now worked on a large scale in the United States, the annual yield far surpassing that of any other part of the world. The most active operations are carried on in Florida, where the phosphate was first worked in 1887 in the form of pebbles in the gravels of Peace River. Then followed the discovery of "hard rock-phosphate," a massive mineral, often having cavities lined with nearly pure phosphorite. Other kinds not distinctly hard and consisting of less rich phosphatic limestone, are known as "soft phosphate": those found as smooth pebbles of variable colour are called "land pebble-phosphate," whilst the pebbles of the river-beds and old river-valleys, usually of dark colour, are distinguished as "river pebble-phosphate." The land pebble is worked in central South Florida; the hard rock chiefly between Albion and Bay City. In South Carolina, where there are important deposits of phosphate, formerly more productive than at present, the "land rock" is worked near Charleston, and the "river rock" in the Coosaw River and other streams near Beaufort. The phosphate beds contain Eocene fossils derived from the underlying strata and many fragments of Pleistocene vertebrata such as mastodon, elephant, stag, horse, pig, &c. The phosphate occurs as lumps varying greatly in size, scattered through a sand or clay; they often contain phosphatized Eocene fossils (Mollusca, &c.). Sometimes the phosphate is found at the surface, but generally it is covered by alluvial sands and clays. Phosphate mining began in South Carolina in 1868, and for twenty years that state was the principal producer. Then the Florida deposits began to be worked. In 1892 the phosphates of Tennessee, derived from Ordovician limestones, came into the market. From North Carolina, Alabama and Pennsylvania, also, phosphates have been obtained but only in comparatively small quantities. In 1900 mining for phosphates was commenced in Arkansas. In 1908 Florida produced 1,673,651 tons of phosphate valued at 11 million dollars. All the other states together produce less phosphate than Florida, and among them Tennessee takes the first place with an output of 403,180 tons.

Algeria contains important deposits of phosphorite, especially near Tebessa and at Tocqueville in the province of Constantine. Near Jebel Kouif, on the frontier between Algeria and Tunis, there are phosphate workings, as also in Tunis, at Gafsa. The deposits belong to the Lower Eocene, where it rests unconformably upon the Cretaceous. The joint production of Tunis and Algeria in 1907 was not less than a million tons. Phosphates occur also in Egypt, in the desert east of Keneh and in the Dakla oasis in the Libyan desert.

France is rich in mineral phosphates, the chief deposits being in the departments of the Pas-de-Calais, Somme, Aisne, Oise and Meuse, in the north-east, and another group in the departments of Lot, Tarn-et-Garonne and Aveyron, in the south-west: phosphates occur also in the Pyrenees. The deposits near Caylus and in Quercy occupy fissures and pockets in Jurassic limestone, and have yielded a remarkable assemblage of the relics of Tertiary mammals and other fossils. Phosphates occur in Belgium, especially near Mons, and these, like those of north-east France, are principally in the Upper Chalk. Two varieties of phosphate rock are recognized in these districts, viz. the phosphatic chalk and the phosphate sand, the latter resulting from the decomposition of the former. Large and valuable deposits of the sand have been obtained in sinks and depressions on the surface of the chalk. The production is on the whole diminishing in Belgium (180,000 tons in 1907), but in France it is still large (375,000 tons in 1907).

In the Lahn district of Nassau (Germany) there are phosphate beds in Devonian rocks. The deposits were rich but irregular and local, and were much worked from 1866 to 1884, but are no longer of economic importance. In northern Estremadura in Spain and Alemtezo in Portugal there are vein deposits of phosphate of lime. As much as 200,000 tons of phosphate have been raised in these provinces, but in 1906 the total production of Spain was only 1300 tons. Large deposits of phosphate occur in Russia, and those in the neighbourhood of Kertch have attracted some attention; it is said that the Cretaceous rocks between the rivers Dniester and Volga contain very large supplies of phosphate, though probably of low grade.

Phosphatic nodules and concretions, with phosphatized fossils and their casts, occur at various geological horizons in Great Britain. Bands of black nodules, highly phosphatic, are found at the top of the Bala limestone in North Wales; beds of concretions occur in the Jurassic series; and important deposits are known in the Cretaceous strata, especially in the Lower Greensand and at the base of the Gault. The Lower Greensand phosphates have been worked, under the name of "coprolites," at Potton in Bedfordshire and at Upware and Wicken in Cambridgeshire. The Cambridge Greensand, rich in phosphatic nodules, occurs at the base of the Chalk Marl. The chalk occasionally becomes phosphatized, as at Taplow (Bucks) and Lewes (Sussex). At the base of the Red Crag in East Anglia, and occasionally at the base of the other Pliocene Crags, there is a "nodule bed," consisting of phosphatic nodules, with rolled teeth and bones, which were formerly worked as "coprolites" for the preparation of artificial manure. Professor R. J. Strutt has found that phosphatized nodules and bones are rich in radioactive constituents, and has brought this into relation with their geological age.

PHOSPHORESCENCE, a name given to a variety of physical phenomena due to different causes, but all consisting in the emission of a pale, more or less ill-defined light, not obviously due to combustion. The word was first used by physicists to describe the property possessed by many substances of themselves becoming luminous after exposure to light. This property has been noticed from early times. Pliny speaks of various gems which shine with a light of their own, and Albertus Magnus knew that the diamond becomes phosphorescent when moderately heated. But the first discovery of this property which apparently attracted scientific attention seems to have been that of the Bologna stone (barium sulphide), which was discovered

condenser, where it is condensed. It is then cast under water. The calcium silicate remains in the furnace in the form of a liquid slag, which may be run off, so that the action is practically continuous. Kaolin may with advantage be used in addition to or in part substitution for sand, because the double silicate thus formed is more fusible than the single silicate of lime. The alternating current is generally used, the action not being electrolytic. One of the special advantages of the electrical over the older process is that the distilling vessels have a longer life, owing to the fact that they are not externally heated, and so subjected to a relatively high temperature when in contact with the corrosive slag formed in the process. The Readman-Parker process (see *Jour. Soc. Chem. Ind.*, 1891, x. 445) appears to be very generally adopted. Readman, experimenting with a Cowles furnace in Staffordshire in 1888, patented his process, and in the same year Parker and Robinson, working independently, patented a similar one. The two inventors then co-operated, an experimental plant was run successfully, and the patents were taken over by the leading manufacturers. With the object of obtaining a valuable by-product in place of the slag produced in this furnace, several patentees (*e.g.* Hilbert and Frank, Billaudot, Bradley and Jacobs, and others) have sought to combine the manufacture of calcium carbide and phosphorus by using only calcium phosphate and carbon, effecting direct reduction by carbon at a high temperature.

The crude phosphorus is purified by melting under water and then filtering through animal black and afterwards through chamois leather, or by treating it, when molten, with chromic acid or a mixture of potassium bichromate and sulphuric acid; this causes the impurities to rise to the surface as a scum which can be skimmed off. It is usually sent on the market in the form of sticks, which were at one time prepared by sucking the molten material up glass tubes; but the dangers to the workmen and other disadvantages of this method have led to its replacement by a continuous process, in which the phosphorus leaves the melting-pot for a pipe surrounded by water, in which it solidifies and can be removed as a continuous rod.

Properties.—When perfectly pure phosphorus is a white, transparent, waxy solid, but as usually prepared it is yellowish owing to the presence of the allotropic "red phosphorus," J. Böeseken (*Abs. Jour. Chem. Soc.*, 1907, ii. 343, 760) prepares perfectly pure phosphorus by heating the crude product with chromic acid solution, washing and drying in a vacuum, first at 40°, then at 80°. It remains colourless in vacuum tubes in the dark, but on exposure it rapidly turns yellow. At 25° to 30° C. it is soft and flexible, but it hardens when strongly cooled, and can then only be cut with difficulty. The fracture is distinctly crystalline; large crystals, either regular dodecahedra or octahedra, may be obtained by crystallization from carbon bisulphide, sulphur chloride, &c., or by sublimation. It is a non-conductor of electricity. Its density at 0° is 1·836; this regularly diminishes up to the melting-point, 44·3°, when a sudden drop occurs. Molten phosphorus is a viscid, oily, highly refractive liquid, which may be supercooled to 32° before solidification. It boils at 290°, forming a colourless vapour which just about the boiling-point corresponds in density to tetratomic molecules, P_4; at 1500° to 1700°, however, Biltz and Meyer detected dissociation into P_2 molecules. Beckmann obtained P_4 molecules from the boiling-point of carbon bisulphide solutions, and Hertz arrived at the same conclusion from the lowering of the freezing-point in benzene solution; E. Paternò and Nasini, however, detected dissociation. Phosphorus is nearly insoluble in water, but dissolves in carbon bisulphide, sulphur chloride, benzene and oil of turpentine.

The element is highly inflammable, taking fire in air at 34° and burning with a bright white flame and forming dense white clouds of the pentoxide; in perfectly dry air or oxygen, however, it may be distilled unchanged, H. B. Baker showing that a trace of water vapour was necessary for combination to occur. When exposed to the air a stick of phosphorus undergoes slow combustion, which is revealed by a greenish-white phosphorescence when the stick is viewed in the dark. This phenomenon was minutely studied by Boyle, who found that solutions in some essential oils (oil of cloves) showed the same character, whilst in others (oils of mace and aniseed) there was no phosphorescence. He also noticed a strong garlic-like odour, which we now know to be due to ozone. Frederick Slare noticed that the luminosity increased when the air was rarefied, an observation confirmed by Hawksbee and Homberg, and which was possibly the basis of Berzelius's theory that the luminosity depended on the volatility of the element and not on the presence of oxygen. Lampadius, however, showed that there was no phosphorescence in a Torricellian vacuum; and other experimenters proved that oxygen was essential to the process. It depends on the partial pressure of the oxygen and also on temperature. In compressed air at ordinary temperature there is no glowing, but it may be brought about by heating. Again, in oxygen under ordinary conditions there is no phosphorescence, but if the gas be heated to 25° glowing occurs, as is also the case if the pressure be diminished or the gas diluted. It is also remarkable that many gases and vapours, *e.g.* Cl, Br, INH_3, N_2O, NO_2, H_2S, SO_2, CS_2, CH_4, C_2H_4, inhibit the phosphorescence.

The theory of this action is not settled. It is certain that the formation of hydrogen peroxide and ozone accompany the glowing, and in 1848 Schonbein tried to demonstrate that it depended on the ozone. E. Jungfleisch (*Comptes rendus*, 1905, 140, p. 444) suggested that it is due to the combustion of an oxide more volatile than phosphorus, a view which appears to be supported by the observations of Scharff (*Zeit. physik. Chem.*, 1908, 62, p. 178) and of L. and E. Bloch (*Comptes rendus*, 1908, 147, p. 842).

The element combines directly with the halogens, sulphur and selenium, and most of the metals burn in its vapour forming phosphides. When finely divided it decomposes water giving hydrogen phosphide; it also reduces sulphurous and sulphuric acids, and when boiled with water gives phosphine and hypophosphorous acid; when slowly oxidized under water it yields hypophosphoric acid.

Allotropic Phosphorus.—Several allotropic forms of phosphorus have been described, and in recent years much work has been done towards settling their identities. When the ordinary form immersed in water is exposed to light, it gradually loses its transparency and becomes coated with a thin film. This substance was regarded as an allotrope, but since it is not produced in non-aerated water it is probably an oxide. More important is the so-called "red phosphorus," which is produced by heating yellow phosphorus to about 230° for 24 hours in an inert atmosphere, or in closed vessels to 300°, when the change is effected in a few minutes. E. Kopp in 1844 and B. C. Brodie in 1853 showed that a trace of iodine also expedited the change. The same form is also produced by submitting ordinary phosphorus to the silent electric discharge, to sunlight or the ultra-violet light. Since this form does not inflame until heated to above 350°, it is manufactured in large quantities for consumption in the match industry. The process consists in heating yellow phosphorus in iron pots provided with air-tight lids, which, however, bear a long pipe open to the air. A small quantity of the phosphorus combines with the oxygen in the vessel, and after this the operation is practically conducted in an atmosphere of nitrogen with the additional safety from any risk of explosion. The product is ground under water, and any unchanged yellow form is eliminated by boiling with caustic soda, the product being then washed and dried and finally packed in tin boxes. The red variety is remarkably different from the yellow. It is a dark red microcrystalline powder, insoluble in carbon bisulphide, oil of turpentine, &c., and having a density of 2·2. It is stable to air and light, and does not combine with oxygen until heated to above 350° in air or 260° in oxygen, forming the pentoxide. It is also non-poisonous. When heated in a vacuum to 530° it sublimes, and on condensation forms microscopic needles.

Hittorf's phosphorus is another crystalline allotrope formed by heating phosphorus with lead in a sealed tube to redness, and removing the lead by boiling the product with nitric and

hydrochloric acid. It is also obtained by heating red phosphorus under pressure to 580°. It forms a lustrous, nearly black crystalline mass, composed of minute rhombohedra. G. E. Linck and P. Möller (*Ber.*, 1908, 41, p. 1404) have affirmed that the product of the first process always contains lead. E. Cohen and J. Olie, jun. (*Abs. Jour. Chem. Soc.*, 1909, ii. 998) regard red phosphorus as a solid solution of the white in Hittorf's, but this is contradicted by A. Stock (*Ber.*, 1909, 42, p. 4510), who points out that ordinary red phosphorus melts at 605°-610°, whilst Hittorf's melts at 620°; moreover, the latter is less reactive than the former at high temperatures.

Another form was obtained by R. Schenck (*Zeit. Elektrochem*, 1905, ii. 117) as a scarlet amorphous powder by deposition of solutions of phosphorus in the tri-iodide, tribromide or sulphide (P_4S_3). It phosphoresces in ozone, but not in air, and is non-poisonous; from its solution in alcoholic potash acids precipitate the hydride $P_{12}H_6$, and when heated it is transformed into the red modification. It has been used in combination with potassium chlorate as a composition for matches to strike on any surface. Finally a black phosphorus was described by Thénard as formed by rapidly cooling melted phosphorus.

Phosphine (phosphoretted hydrogen), PH_3, a gas formed in the putrefaction of organic matter containing phosphorus, was obtained by Gengembre (*Crell's Ann.*, 1789, i. 450) by the action of potash upon phosphorus, the gas so prepared being spontaneously inflammable. Some time later Davy, by heating phosphorous acid, obtained a phosphoretted hydrogen which was not spontaneously inflammable. These gases were considered to be distinct until Le Verrier (*Ann. chim. phys.*, 1835 [2], 60, p. 174) showed that the inflammability of Gengembre's phosphine was due to small quantities of liquid phosphoretted hydrogen, P_2H_4. Phosphine may be prepared by the decomposition of calcium phosphide with water (P_2H_4 being formed simultaneously); by the decomposition of phosphorous and hypophosphorous acids when strongly heated; and by the action of solutions of the caustic alkalis on phosphorus: $P_4 + 3NaOH + 3H_2O = PH_3 + 3NaH_2PO_2$; hydrogen and P_2H_4 are produced at the same time, and the gas may be freed from the latter substance by passing into a hydrochloric acid solution of cuprous chloride, and heating the solution, when pure phosphine is liberated (Riban, *Comptes rendus*, 5?, p. 581). The pure gas may also be obtained by heating phosphonium iodide with caustic potash (A. W. Hofmann, *Ber.*, 1871, 4, p. 200); by the decomposition of crystalline calcium phosphide or of aluminium phosphide with water (H. Moissan, *Bull. soc. chim.*, 1899 (3), 21, p. 926; Matignon, *Comptes rendus*, 1900, 130, p. 1391); and by the reduction of phosphorous acid with nascent hydrogen.

It is a colourless, extremely poisonous gas, possessing a characteristic offensive smell, resembling that of rotting fish. It becomes liquid at -90° C., and solid at -133° C. (K. Olszewski, *Monats.*, 1886, 7, p. 371). It is only slightly soluble in water, but is readily soluble in solutions of copper sulphate, hypochlorous acid, and acid solutions of cuprous chloride. It burns with a brightly luminous flame, and is spontaneously inflammable at about 100° C. When mixed with oxygen it combines explosively if the mixture be under diminished pressure, and is violently decomposed by the halogens. It is also decomposed when heated with sulphur or with most metals, in the latter case with the liberation of hydrogen and formation of phosphide of the metal. It combines with the halide derivatives of boron and silicon to form, *e.g.* $PH_3{\cdot}2BF_3$, $2PH_3{\cdot}SiCl_4$ (Besson, *Comptes rendus*, 1890, 110, 80, pp. 240, 516; 1891, 113, p. 78), with the halogen acids to form phosphonium salts, PH_4X (X = Cl,Br,I), and with sodammonium and potassammonium to form PH_2Na, PH_2K (Joannis, *Comptes rendus*, 1894, 119, p. 557). It oxidizes slowly in air, and is a reducing agent. It decomposes when heated, hydrogen and red phosphorus being formed.

Liquid Phosphoretted Hydrogen, P_2H_4, first obtained by P. Thénard (*Comptes rendus*, 1844, 18, p. 652) by decomposing calcium phosphide with warm water, the products of reaction being then passed through a U tube surrounded by a freezing mixture (see also L. Gattermann, *Ber.*, 1890, 23, p. 1174). It is a colourless liquid which boils at 57°-58° C. It is insoluble in water, but soluble in alcohol and ether. It is very unstable, being readily decomposed by heat or light. By passing the products of the decomposition of calcium phosphide with water over granular calcium chloride, the P_2H_4 gives a new hydride, $P_{12}H_6$ and phosphine, the former being an odourless, canary-yellow, amorphous powder. When heated in a vacuum it evolves phosphine, and leaves an orange-red residue of a second new hydride, P_9H_2 (A. Stock, W. Böttcher, and W. Lenger, *Ber.*, 1909, 42, pp. 2839, 2847, 2853).

Solid Phosphoretted Hydrogen, P_4H_2, first obtained by Le Verrier (*loc. cit.*), is formed by the action of phosphorus trichloride on gaseous phosphine (Besson, *Comptes rendus*, 111, p. 972); by the action of water on phosphorus di-iodide and by the decomposition of calcium phosphide with hot concentrated hydrochloric acid. It is a yellow solid, which is insoluble in water. It burns when heated to about 200° C. Oxidizing agents decompose it with great violence. When warmed with alcoholic potash it yields gaseous phosphine, hydrogen and a hypophosphite. It reduces silver salts.

Phosphonium Salts.—The *chloride*, PH_4Cl, was obtained as a crystalline solid by Ogier (*Comptes rendus*, 1879, 89, p. 705) by combining phosphine and hydrochloric acid gas under a pressure of from 14–20 atmospheres; it can also be obtained at -30° to -35° C. under ordinary atmospheric pressure. It crystallizes in large transparent cubes, but rapidly dissociates into its constituents on exposure. The *bromide*, PH_4Br, was first obtained by H. Rose (*Pogg. Ann.*, 1832, 24, p. 151) from phosphine and hydrobromic acid; it also results when phosphorus is heated with hydrobromic acid to 100–120° C. in sealed tubes (Damoiseau, *Bull. soc. chim.*, 1881, 35, p. 49). It crystallizes in colourless cubes, is deliquescent, and often inflames spontaneously on exposure to air. It is readily decomposed by water and also by carbonyl chloride (Besson, *Comptes rendus*, 1896, 122, p. 140): $6PH_4Br + 5COCl_2 = 10HCl + 5CO + 6HBr + 2PH_3 + P_4H_2$. The *iodide*, PH_4I, first prepared by J. Gay-Lussac (*Ann. chim. phys.*, 1814, 91, p. 14), is usually obtained by the action of water on a mixture of phosphorus and iodine (A. W. Hofmann, *Ber.*, 1873, 6, p. 286). It is also prepared by the action of iodine on gaseous phosphine, or by heating amorphous phosphorus with concentrated hydriodic acid solution to 160° C. It crystallizes in large cubes and sublimes readily. It is a strong reducing agent. Water and the caustic alkalis readily decompose it with liberation of phosphine and the formation of iodides or hydriodic acid. It is also decomposed by carbonyl chloride (Besson, *loc. cit.*).

$$4PH_4I + 8COCl_2 = 16HCl + 8CO + P_2I_4 + 2P.$$

Just as the amines are derived from ammonia, so from phosphine are derived the primary, secondary and tertiary organic phosphines by the exchange of hydrogen for alkyl groups, and corresponding to the phosphonium salts there exists a series of organic phosphonium bases. The primary and secondary phosphines are produced when the alkyl iodides are heated with phosphonium iodide and zinc oxide to 150° C. (A. W. Hofmann, *Ber.*, 1871, 4, pp. 430, 605), thus: $2RI + 2PH_4I + ZnO = 2R{\cdot}PH_2{\cdot}HI + ZnI_2 + H_2O$, $2RI + PH_4I + ZnO = R_2{\cdot}PH{\cdot}HI + ZnI_2 + H_2O$. The reaction mixture on treatment with water yields the primary phosphine, the secondary phosphine being then liberated from its hydriodide by caustic soda. The tertiary phosphines, discovered by L. Thénard (*Comptes rendus*, 1845, 21, p. 144; 1847, 25, p. 892), are formed (together with the quaternary phosphonium salts) by heating alkyl iodides with phosphonium iodide to 150–180° C.: $PH_4I + 3CH_3I = P(CH_3)_3HI + 3HI$; $P(CH_3)_3HI + CH_3I = P(CH_3)_4I + HI$ (see also Fireman, *Ber.*, 1897, 30, p. 1088). They are also formed by the interaction of phosphorus trichloride and zinc alkyls (Cahours and Hofmann, *Ann.*, 1857, 104, p. 1): $2PCl_3 + 3Zn(C_2H_5)_2 = 3ZnCl_2 + 2P(C_2H_5)_3$.

The primary and secondary phosphines are colourless compounds, and with the exception of methyl phosphine are liquid at ordinary temperature. They possess an unpleasant odour, fume on exposure to air, show a neutral reaction, but combine with acids to form salts. They oxidize very rapidly on exposure, in many cases being spontaneously inflammable. On oxidation with nitric acid the primary compounds give monoalkyl phosphinic acids, $R{\cdot}PO(OH)_2$, the secondary yielding dialkyl phosphinic acids, $R_2PO(OH)$. The primary phosphines are very weak bases, their salts with acids being readily decomposed by water. The tertiary phosphines are characterized by their readiness to pass into derivatives containing pentavalent phosphorus, and consequently they form addition compounds with sulphur, carbon bisulphide, chlorine, bromine, the halogen acids and the alkyl halides with great readiness. On oxidation they yield phosphine oxides, $R_3P{\cdot}O$. The quaternary phosphonium salts resemble the corresponding nitrogen compounds. They are stable towards aqueous alkalis, but on digestion with moist silver oxide yield the phosphonium hydroxides, which are stronger bases than the caustic alkalis. They differ from the organic ammonium hydroxides in their behaviour when heated, yielding phosphine oxides and paraffin hydrocarbons: $R_4P{\cdot}OH = R_3PO + RH$. The boiling-points of some members of the series are shown in the table:—

	Primary.	Secondary.	Tertiary.
Methyl . . .	− 14° C.	25° C.	40–42° C.
Ethyl . . .	+ 25° C.	85° C.	128° C.
Isopropyl . . .	41° C.	118° C.	—
Isobutyl . . .	62° C.	153° C.	215° C.
Isoamyl . . .	107° C.	210–215° C.	300° C. (?)

The alkyl phosphinic acids are colourless crystalline compounds which are easily soluble in water and alcohol. They yield two series of salts, viz. $RHM{\cdot}PO_3$ and RM_2PO_3 (M = metal). The dialkyl phosphinic acids are also colourless compounds, the majority of which are insoluble in water. They yield only one series of salts.

Oxides.—Phosphorus forms three well-defined oxides, P_4O_6, P_2O_4 and P_2O_5; two others, P_4O and P_2O, have been described.

Phosphorus suboxide, P_4O, is said to be formed, mixed with the

other oxides, when the element is burnt in a limited supply of air or in pure oxygen under reduced pressure (E. Jungfleisch, *Abs. Jour. Chem. Soc.*, 1907, ii. 761), and also when a solution of phosphorus in the trichloride or tribromide is exposed to light. It is a yellow or red powder which becomes dark red on heating; it is stable in air, and can be heated to 300° without decomposition. Its existence, however, has been denied by A. Stock (*Abs. Jour. Chem. Soc.*, 1910, ii. 121). The oxide P_2O was obtained by Besson (*Comptes rendus*, 1897, 124, p. 763; 1901, pp. 132, 1556) by heating a mixture of phosphonium bromide and phosphorus oxychloride in sealed tubes to 50°.

Phosphorus oxide, P_4O_6, discovered by Sage in 1777, is a product of the limited combustion of phosphorus in air. It may be conveniently prepared by passing a rapid current of air over burning phosphorus contained in a combustion tube, and condensing the product in a metal condenser, from which it may be removed by heating the condenser to 50°–60° (Thorpe and Tutton, *Jour. Chem. Soc.*, 1890, pp. 545, 632; 1891, p. 1019). Jungfleisch has obtained it by carrying out the combustion with oxygen under reduced pressure, or diluted with an inert gas. It forms crystals, apparently monoclinic, which melt at 22·5° to a clear, colourless, mobile liquid of boiling-point 173·1°. Its specific gravity is 2·135 at 21°. Vapour density and cryoscopic determinations point to the double formula, P_4O_6. It is comparatively stable up to 200°, but when heated in a sealed tube to 440° it gives phosphorus and the tetroxide P_2O_4. It is unaffected by light when pure, but if phosphorus be present, even in minute quantity, it turns yellow and ultimately dark red. It oxidizes on exposure to air to the pentoxide, and with a brilliant inflammation when thrown into oxygen at 50°–60°. It slowly reacts with cold water to form phosphorous acid; but with hot water it is energetically decomposed, giving much red phosphorus or the suboxide being formed with an explosive evolution of spontaneously inflammable phosphoretted hydrogen; phosphoric acid is also formed. With dilute alkalis phosphites are slowly formed, but with concentrated solutions the decomposition follows the same course as with hot water. With chlorine it gives phosphoryl and "metaphosphoryl" chlorides, the action being accompanied with a greenish flame; bromine gives phosphorus pentabromide and pentoxide which interact to give phosphoryl and "metaphosphoryl" bromides; iodine gives phosphorus di-iodide, P_2I_4, and pentoxide, P_2O_5; whilst hydrochloric acid gives phosphorus trichloride and phosphorous acid, which interact to form free phosphorus, phosphoric acid and hydrochloric acid. It combines violently with sulphur at 160° to form *phosphorus sulphoxide*, $P_4O_6S_4$, which forms highly lustrous tetragonal plates (after sublimation), melting at 102° and boiling at 295°; it is decomposed by water into sulphuretted hydrogen and metaphosphoric acid, the latter changing on standing into orthophosphoric acid. Sulphur trioxide and sulphuric acid oxidize phosphorus oxide, giving the pentoxide and sulphur dioxide, whilst sulphur chloride, S_2Cl_2, gives phosphoryl and thiophosphoryl chlorides, free sulphur and sulphur dioxide. Ammonia also reacts immediately, giving phosphorus diamide, $P(OH)(NH_2)_2$, and the corresponding ammonium salt. Phosphorus oxide is very poisonous, and is responsible for the caries set up in the jaws of those employed in the phosphorus industries (see below). It is probable, however, that pure phosphorus oxide vapour is odourless, and the odour of phosphorus as ordinarily perceived is that of a mixture of the oxide with ozone.

Phosphorus tetroxide, P_2O_4, was obtained by Thorpe and Tutton by heating the product of the limited combustion of phosphorus *in vacuo* as a sublimate of transparent, highly lustrous, orthorhombic crystals. They are highly deliquescent, and form with water a mixture of phosphorous and phosphoric acids: $P_2O_4+3H_2O=H_3PO_3+H_3PO_4$. The vapour density at about 1400° is 230, *i.e.* slightly less than that required by P_8O_{16} (West, *Jour. Chem. Soc.*, 1902, p. 923).

Phosphoric oxide, or *phosphorus pentoxide*, P_4O_{10}, formed when phosphorus is burned in an excess of air or oxygen, or from dry phosphorus and oxygen at atmospheric pressure (Jungfleisch, *loc. cit.*), was examined by Boyle and named "flowers of phosphorus" by Marggraf in 1740. It is a soft, flocculent powder, which on sublimation forms transparent, monoclinic crystals. It is extremely deliquescent, hissing when thrown into water, with which it combines to form phosphoric acid. It is reduced when heated with carbon to phosphorus, carbon monoxide being formed simultaneously. Its vapour density at 1400° points to the double formula (West, *Jour. Chem. Soc.*, 1896, p. 154).

Oxyacids.—Phosphorus forms several oxyacids: hypophosphorous acid, H_3PO_2, and hypophosphoric acid, $H_4P_2O_6$ or H_2PO_3, of which the anhydrides are unknown; phosphorous acid, H_3PO_3, derived from P_4O_6; monoperphosphoric acid, H_3PO_5; perphosphoric acid, $H_4P_2O_8$; and meta-, pyro-, and ortho-phosphoric acids, derived from P_4O_{10}, for which see PHOSPHATES.

Hypophosphorous acid, $HP(OH)_2$, discovered by Dulong in 1816, and obtained crystalline by Thomson in 1874 (*Ber.* 7, p. 994), is prepared in the form of its barium salt by warming phosphorus with baryta water, removing the excess of baryta by carbon dioxide, and crystallizing the filtrate. The acid may be prepared by evaporating in a vacuum the solution obtained by decomposing the barium salt with the equivalent amount of sulphuric acid. The acid forms a white crystalline mass, melting at 17·4° and having a strong acid reaction. Exposure to air gives phosphorous and phosphoric acids, and on heating it gives phosphine and phosphoric acid. A characteristic reaction is the formation of a red precipitate of cuprous hydride, Cu_2H_2, when heated with copper sulphate solution to 60°. It is a monobasic acid forming salts which are permanent in air, but which are gradually oxidized in aqueous solution. On heating they yield phosphine and leave a residue of pyrophosphate, or a mixture of meta- and pyrophosphates, with a little phosphorus. They react as reducing agents. On boiling with caustic potash they evolve hydrogen, yielding a phosphate.

Phosphorous acid, $P(OH)_3$, discovered by Davy in 1812, may be obtained by dissolving its anhydride, P_4O_6, in cold water; by immersing sticks of phosphorus in a solution of copper sulphate contained in a well-closed flask, filtering from the copper sulphide and precipitating the sulphuric acid simultaneously formed by baryta water, and concentrating the solution *in vacuo*; or by passing chlorine into melted phosphorus covered with water, the first formed phosphorus trichloride being decomposed by the water into phosphorous and hydrochloric acids. It may also be prepared by leading a current of dry air into phosphorus trichloride at 60° and passing the vapours into water at 0°, the crystals thus formed being drained, washed with ice-cold water and dried in a vacuum. The crystals melt at 70°. The acid is very deliquescent, and oxidizes on exposure to air to phosphoric acid. It decomposes on heating into phosphine and phosphoric acid. It is an energetic reducing agent; for example, when boiled with copper sulphate metallic copper is precipitated and hydrogen evolved. Although nominally tribasic the commonest metallic salts are dibasic. Organic ethers, however, are known in which one, two and three of the hydrogen atoms are substituted (Michaelis and Becker, *Ber.*, 1897, 30, p. 1003). The metallic phosphites are stable both dry and in solution; when strongly heated they evolve hydrogen and yield a pyrophosphate, or, especially with the heavy metals, they give hydrogen and a mixture of phosphide and pyrophosphate.

Hypophosphoric acid, $H_4P_2O_6$ or H_2PO_3, discovered by Salzer in 1877 among the oxidation products of phosphorus by moist air, may be prepared by oxidizing phosphorus in an aqueous solution of copper nitrate, or by oxidizing sticks of phosphorus under water, neutralizing with sodium carbonate, forming the lead salt and decomposing this with sulphuretted hydrogen (J. Cavalier and E. Cornec, *Abs. Jour. Chem. Soc.*, 1910, ii. 31). The aqueous solution may be boiled without decomposition, but on concentration it yields phosphorous and phosphoric acids. Deliquescent, rectangular tablets of $H_4P_2O_6 2H_2O$ separate out on concentrating a solution in a vacuum, which on drying further give the acid, which melts at 55°, and decomposes suddenly when heated to 70° into phosphorous and metaphosphoric acids with a certain amount of hydrogen phosphide. The solution is stable to oxidizing agents such as dilute hydrogen peroxide and chlorine, but is oxidized by potassium permanganate to phosphoric acid; it does not reduce salts of the heavy metals. With silver nitrate it gives a white precipitate, $Ag_4P_2O_6$. The sodium salt, $Na_4P_2O_6 \cdot 10H_2O$, forms monoclinic prisms and in solution is strongly alkaline; the acid salt, $Na_3HP_2O_6 \cdot 9H_2O$, forms monoclinic tablets. The formula of the acid is not quite definite. Cryoscopic measurements on the sodium salt points to the double formula, but the organic esters appear to be derived from H_2PO_3 (see A. Rosenheim and M. Pritze, *Ber.*, 1908, 41, 2708; E. Cornec, *Abs. Jour. Chem. Soc.*, 1910, ii. 121).

Monoperphosphoric and *perphosphoric acids*, H_3PO_5 and $H_4P_2O_8$, were obtained by J. Schmidlin and P. Massini (*Ber.*, 1910, 43, 1162). The first is formed when 30% hydrogen peroxide reacts with phosphorus pentoxide or meta- or pyro-phosphoric acids at low temperatures and the mixture diluted with ice-cold water. The solution is strongly oxidizing, even converting manganous salts to permanganates in the cold, a property not possessed by monopersulphuric acid. Perphosphoric acid is formed when pyrophosphoric acid is treated with a large excess of hydrogen peroxide.

Halogen Compounds.—*Phosphorus trifluoride*, PF_3, discovered by Davy, may be obtained mixed with the pentafluoride; by direct combination of its elements; from the tribromide and arsenic trifluoride (MacIvor); from the tribromide and zinc fluoride, and from dried copper phosphide and lead fluoride (H. Moissan). It is a colourless, non-fuming gas, which gives a colourless, mobile liquid at −10° and 20 atmospheres; the liquid boils at −95° and solidifies at −160° (Moissan, *Comptes rendus*, 1904, 138, p. 789). It does not burn in air, but explodes, under the action of a flame or the electric spark, when mixed with half its volume of oxygen, giving the oxyfluoride, POF_3. It is slowly decomposed by water giving hydrofluoric and phosphorous acids, or, in addition, fluorphosphorous acid, HPF_4. It has no action on glass in the cold, but when heated it gives phosphorus and silicon tetrafluoride. *Phosphorus pentafluoride*, PF_5, discovered by Thorpe (*Proc. Roy. Soc.*, 1877, 25, p. 122), may be obtained by burning the trifluoride in fluorine, from the pentachloride and arsenic trifluoride and from the trifluoride and bromine, the first formed fluorobromide, PF_3Br_2, decomposing into the pentabromide and pentafluoride: $5PF_3Br_2 = 3PF_5 + 2PBr_5$. It is a colourless gas $4\frac{1}{2}$ times heavier than air, and liquefies at 15° under 40 atmospheres, solidifying when the pressure is diminished. It is incombustible and extinguishes flame. It fumes in moist air and is quickly decomposed by water giving hydrofluoric and phosphoric

acids. It does not dissociate on heating as do the pentachloride and pentabromide, thus indicating the existence of pentavalent phosphorus in a gaseous compound; dissociation, however, into the trifluoride and free fluorine may be brought about by induction sparks of 150 to 200 mm. in length. It combines directly with ammonia in the proportion $2PF_5 : 5NH_3$, and with nitrogen peroxide at -10° in the proportion $2PF_5 : NO_2$. *Phosphorus trifluorodichloride*, PF_3Cl_2, prepared from chlorine and the trifluoride, is a pungent-smelling gas, which at 250° gives the pentachloride and fluoride. The *trifluorodibromide* (see above) is an amber-coloured mobile liquid. *Phosphoryl trifluoride*, POF_3, may be obtained by exploding 2 volumes of phosphorus trifluoride with 1 volume of oxygen (Moissan, 1886); by heating 2 parts of finely divided cryolite and 3 parts of phosphorus pentoxide (Thorpe and Hambly, *Jour. Chem. Soc.*, 1889, p. 759); or from phosphoryl chloride and zinc fluoride at 40° to 50°. It is a colourless fuming gas, which liquefies under ordinary pressure at -50°, and under a pressure of 15 atmospheres at 16°; it may be solidified to a snow-like mass. Water gives hydrofluoric and phosphoric acids. The corresponding sulphur compound, thiophosphoryl fluoride, PSF_3, obtained by heating lead fluoride and phosphorus pentasulphide to 200°, is a colourless gas, which may be condensed to a clear transparent liquid. It spontaneously inflames in air or oxygen; and when the gas is issuing from a jet into air the flame is greyish green, with a faintly luminous and yellow tip; the flame is probably one of the coldest known. The combustion probably follows the equation $PSF_3 + O_2 = PF_3 + SO_2$, the trifluoride at a higher temperature decomposing according to the equations: $10PF_3 + 5O_2 = 6PF_5 + 2P_2O_5$, $2PF_3 + O_2 = 2POF_3$, the complete reaction tending to the equation: $10PSF_3 + 15O_2 = 6PF_5 + 2P_2O_5 + 10SO_2$. The gas dissolves in water on shaking; $PSF_3 + 4H_2O = H_2S + H_3PO_4 + 3HF$, but is more readily taken up by alkaline solutions with the formation of fluoride and thiophosphate: $PSF_3 + 6NaOH = Na_3PSO_3 + 3NaF$. Heated in a glass tube it gives silicon fluoride, phosphorus and sulphur, $PSF_3 = PF_3 + S$; $4PF_3 + 3SiO_2 = 3SiF_4 + P_4 + 3O_2$. Electric sparks give at first free sulphur and the trifluoride, the latter at a higher temperature splitting into the pentafluoride and phosphorus. With dry ammonia it gives ammonium fluoride and a compound $P(NH_2)_2SF$.

Phosphorus trichloride or *phosphorous chloride*, PCl_3, discovered by Gay-Lussac and Thénard in 1808, is obtained by passing a slow current of chlorine over heated red phosphorus or through a solution of ordinary phosphorus in carbon disulphide (purifying in the latter case by fractional distillation). It is a colourless, mobile liquid of specific gravity 1·6128 at 0° and boiling-point 76°. With chlorine it gives the pentachloride, PCl_5, and with oxygen when heated phosphoryl chloride, $POCl_3$. Water gives hydrochloric and phosphorous acids, with separation of red phosphorus if the water be hot. When led with hydrogen into liquid ammonia it gives $NH : PNH_2$, which on elevation of temperature gives $P_2(NH)_3$ (Joannis, *Comptes rendus*, 1904, 139, p. 364). By submitting a mixture of phosphorus chloride and hydrogen to an electric discharge A. Besson and A. Fournier (*Comptes rendus*, 1901, 150, p. 102) obtained phosphorus dichloride, P_2Cl_4, as a colourless, oily, strongly fuming liquid, freezing at -28° and boiling at 180° with decomposition. With water it gave phosphorous acid and a yellow indefinite solid. It decomposes slowly at ordinary temperatures. *Phosphorus pentachloride*, PCl_5, discovered by Davy in 1810 and analysed by Dulong in 1816, is formed from chlorine and the trichloride. It is a straw-coloured solid, which by fusion under pressure gives prismatic crystals. It sublimes when heated, but under pressure it melts at 148°, giving a normal vapour density, but on further heating it dissociates into the trichloride and chlorine; this dissociation may be retarded by vapourizing in an atmosphere of chlorine. It fumes strongly in moist air, giving hydrochloric acid and phosphoryl chloride, $POCl_3$; with water it gives phosphoric and hydrochloric acids.

Phosphoryl trichloride or *phosphorus oxychloride*, $POCl_3$, corresponding to phosphoric acid, $(HO)_3PO$, discovered in 1847 by Wurtz, may be produced by the action of many substances containing hydroxy groups on the pentachloride; from the trichloride and potassium chlorate; by leaving phosphorus pentoxide in contact with hydrochloric acid: $2P_2O_5 + 3HCl = POCl_3 + 3HPO_3$; or by heating the pentachloride and pentoxide under pressure: $3PCl_5 + P_2O_5 = 5POCl_3$. It is a colourless liquid, boiling at 107·2°, and when solidified it melts at 0·8°. Water gives hydrochloric and phosphoric acids; dilute alcohol gives monoethyl phosphoric acid, $C_2H_5 \cdot H_2PO_4$, whilst absolute alcohol gives triethyl phosphate, $(C_2H_5)_3PO_4$. *Pyrophosphoryl chloride*, $P_2O_3Cl_4$, corresponding to pyrophosphoric acid, was obtained by Geuther and Michaelis (*Ber.*, 1871, 4, p. 766) in the oxidation of phosphorus trichloride with nitrogen peroxide at low temperature; it is a colourless fuming liquid which boils at about 212° with some decomposition. With water it gives phosphoric and hydrochloric acids. *Thiophosphoryl chloride*, $PSCl_3$, may be obtained by the direct combination of sulphur with the trichloride; from sulphuretted hydrogen and the pentachloride; from antimony trisulphide and the pentachloride; by heating the pentasulphide with the pentachloride; and by dissolving phosphorus in sulphur chloride and distilling the solution: $2P + 3S_2Cl_2 = 4S + 2PSCl_3$; it is a colourless mobile liquid, boiling at 125·1° and having a pungent, slightly aromatic odour. It is slowly decomposed by water giving phosphoric and hydrochloric acids, with sulphuretted hydrogen; alkalis form a thiophosphate, *e.g.* $PS(OK)_3$, and a chloride.

Phosphorus tribromide, PBr_3, prepared by mixing solutions of its elements in carbon disulphide and distilling, is a transparent, mobile liquid, boiling at 173° and resembling the trichloride chemically. The *pentabromide*, PBr_5, which results from phosphorus and an excess of bromine, is a yellow solid, and closely resembles the pentachloride. The *bromochloride*, PCl_3Br_2, is an orange-coloured solid formed from bromine and the trichloride, into which components it decomposes at 35°. *Phosphoryl tribromide*, $POBr_3$, is a solid, melting at 45° and boiling at 195°. *Thiophosphoryl bromide*, $PSBr_3$, obtained after the manner of the corresponding chloride, forms yellow octahedra which melt at 38°, and have a penetrating, aromatic odour. With water it gives sulphur, sulphuretted hydrogen, hydrobromic, phosphorous and phosphoric acids, the sulphur and phosphorous acid being produced by the interaction of the previously formed sulphuretted hydrogen and phosphoric acid. *Pyrophosphoryl thiobromide*, $(PBr_2S)_2S$, and *metaphosphoryl thiobromide*, PS_2Br, are also known.

Phosphorus forms three iodides. The subiodide, P_4I, was obtained by R. Boulough (*Comptes rendus*, 1905, 141, p. 256), who acted with dry iodine on phosphorus dissolved in carbon disulphide; with alkalis it gives $P_4(OH)$. The di-iodide and tri-iodide are formed similarly; the first is deposited as orange-coloured prisms which melt at 110° to a red liquid (see Doughty, *Jour. Amer. Chem. Soc.*, 1905, 27, p. 1444), whilst the second forms dark-red hexagonal plates which melt at 55°.

Sulphides and Thio-acids.—Phosphorus and sulphur combine energetically with considerable rise of temperature to form sulphides. The researches of A. Stock (*Ber.*, 1908, 41, pp. 558, 657; 1909, 42, p. 2062; 1910, 43, pp. 150, 414) show that three exist, P_4S_3, P_4S_7, P_2S_5. The first is prepared by heating red phosphorus with finely powdered sulphur in a tube sealed at one end and filled with carbon dioxide. The product is extracted with carbon disulphide and the residue distilled in carbon dioxide. It forms light yellow crystals from benzene, which melt at 172·5° and boil at 407°–408° with slight decomposition. Alkalis give hydrogen and phosphine. The second, P_4S_7, is obtained by heating a mixture of red phosphorus and sulphur in the proportions given by $P_4S_7 + 5$ % P_4S_3, and crystallizing from carbon disulphide in which P_4S_3 is readily soluble. It forms small, slightly yellow prisms, which melt at 310° and boil at 523°. The third, or pentasulphide, P_2S_5, was obtained as a substance resembling flowers of sulphur by A. Stock and K. Thiel (*Ber.*, 1905, 38, p. 2719; 1910, 43, p. 1223), who heated sulphur with phosphorus in carbon disulphide solution with a trace of iodine to 120°–130°. It exists in two forms, one having the formula P_4S_{10}, and the other a lower molecular weight. With liquid ammonia it gives $P_2S_5 \cdot 7NH_3$, which is a mixture of ammonium iminotrithiophosphate, $P(SNH_4)_3 : NH$, and ammonium nitrilodithiophosphate, $P(SNH_4)_2 : N$. Water converts the former into ammonium thiophosphate, $PO(SNH_4)_3 \cdot H_2O$, whilst the latter heated to 300° in a vacuum gives thiophosphoric nitrile, $N:P:S$ (Stock, ibid., 1906, 39, p. 1967).

Thiophosphates result on dissolving the pentasulphide in alkalis. Sodium monothiophosphate, $Na_3PSO_3 \cdot 12H_2O$, is obtained by adding one P_2S_5 to six NaOH, adding alcohol, dissolving the precipitate in water and heating to 90°. On cooling the salt separates as white six-sided tablets. Sodium dithiophosphate, $Na_3PS_2O_2 \cdot 11H_2O$, is obtained by heating the above solution only to 50°–55°, cooling and adding alcohol, which precipitates the dithio salt. On heating it gives the monothio salt. Sodium trithiophosphate appears to be formed when the pentasulphide acts with sodium hydrosulphide at 20°. All thiophosphates are decomposed by acids giving sulphuretted hydrogen and sometimes free sulphur. They also act in many cases as reducing agents.

Nitrogen Compounds.—Phosphorus pentachloride combines directly with ammonia, and the compound when heated to redness loses ammonium chloride and hydrochloric acid and gives phospham, PN_2H, a substance first described by Davy in 1811. It is a white, infusible, very stable solid, which decomposes water on heating, giving ammonia and metaphosphoric acid, whilst alkalis give an analogous reaction. With methyl and ethyl alcohols it forms secondary amines (Vidal, *Comptes rendus*, 1891, 112, p. 950; 1892, 115, p. 123). The diamide, PN_3H_4, was obtained by Hugot (ibid., 1905, 141, p. 1235) by acting with ammonia gas on phosphorus tribromide or tri-iodide at -70°; it is very unstable, and decomposes at -25°. Phosphorus combines with nitrogen and chlorine to form several polymeric substances of the general formula $(PNCl_2)x$, where x may be 1, 3, 4, 5, 6, 7, or 11; they may be obtained by heating the pentachloride with ammonium chloride in a sealed tube and separating the mixture by fractional distillation (H. N. Stokes, *Amer. Chem. Jour.*, 1898, 20, p. 740; also see Besson and Rosset, *Comptes rendus*, 1906, 37, p. 143). The commonest form is $P_3N_3Cl_6$, a crystalline solid, insoluble in water, but soluble in alcohol and ether. Several phosphoamides have been described. The diamide, $PO(NH_2)(NH)$, results when the pentachloride is saturated with ammonia gas and the first formed chlorophosphamide, $PCl_3(NH_2)_2$, is decomposed by water. The triamide, $PO(NH_2)_3$, results from ammonia and phosphorus oxychloride. Both these compounds on heating give phosphomonamide, PON, of which a polymer $(PON)_2$ had been described by Oddo (*Gazz. chim. Ital.*, 1899, 29 (ii.), p. 330). Stokes (*Amer. Chem. Jour.*,

893, 15, p. 198; 1894, 16, pp. 123, 154) has described $PO(OH)_2NH_2$ nd $PO(OH)(NH_2)_2$, whilst the compound $PO(OH)NH$ was obtained y Schiff (*Ann.*, 1857, 103, p. 168) by acting with ammonia on the entoxide. Numerous other nitrogen compounds have been btained.

The atomic weight of phosphorus was determined by Berzelius, Pelouze, Jacquelin, Dumas, Schrötter, Brodie and van der Plaats. More recent are the investigations of G. Ter Gazarian (*Compt. rend.*, 909, 148, p. 1397) on hydrogen phosphide, which gave the value 0·906, and of G. P. Baxter and G. Jones (*Jour. Amer. Chem. Soc.*, 910, 32, p. 298) on silver phosphate, which gave the value 31·04.

Therapeutics.—The phosphorus used in the British Pharmacopoeia is obtained from calcium phosphate, and is a waxlike non-metallic substance soluble in oils and luminous in the dark. There are various medicinal preparations. In young animals phosphorus has a remarkable influence on the growth of bone, causing a proliferation of the jelly-like masses and finally a deposit in them of true bony material. Owing to this influence it has been used in rickets and osteomalacia. Its most effective use, however, is as a nerve tonic in paralysis agitans, locomotor ataxia, impotence and nervous exhaustion. In some skin diseases such as psoriasis, chronic eczema and acne indurata, phosphorus is very useful, and cases of diabetes mellitus and lymphadenoma have improved under some of its compounds. The hypophosphites have been recommended in pulmonary affections, being said to act as free phosphorus without being irritant, and the glycero-phosphates are certainly useful to stimulate metabolism. Dilute phosphoric acid is used as a gastric stimulant. It does not resemble phosphorus in its physiological action and cannot be used to replace it.

Toxicology.—Poisonous amounts of phosphorus are frequently taken or administered, criminally or accidentally, it being easily accessible to the public in the form of matches or of vermin pastes. They may have been swallowed several hours before symptoms of acute poisoning show themselves, with nausea and vomiting, and a burning in the oesophagus, stomach and abdomen. The important thing is to prevent the absorption of the poison, so emetics and purgatives should be given at once. Sulphate of copper, in doses of 3 to 5 gr., freely diluted and repeated every few minutes forms the harmless, black phosphide of copper, which is rapidly eliminated by the kidneys. The stomach may be washed out with warm water and then with a 2 % solution of permanganate of potash, an enema of the same solution being given. The old French oil of turpentine is the best antidote to use in phosphorus poisoning, delaying the toxic effects; but ordinary oils are not only useless but harmful. When some time has elapsed before treatment and the phosphorus has become absorbed, the organic degenerative changes cannot be easily controlled. For the chronic form of industrial poisoning in the manufacture of lucifer matches—a form of necrosis, known in England as "phossy jaw" and in France as *mal chimique*, a localized inflammatory infection of the periosteum, ending with the death and exfoliation of part of the bone. (See MATCH.)

PHOTIUS (*c.* 820–891), patriarch of Constantinople (858–867 and 878–886). From his early years he displayed an extraordinary talent and appetite for knowledge, and as soon as he had completed his own education he began to teach with distinguished success grammar, rhetoric, divinity and philosophy. The way to public life was probably opened for him by the marriage of his brother Sergius to the princess Irene, sister of Theodora, who, upon the death of her husband Theophilus in 842, had assumed the regency of the empire. Photius became captain of the guard and subsequently first imperial secretary. The dissensions between the patriarch Ignatius and Bardas, the uncle of the youthful emperor Michael III., brought promotion to Photius. Ignatius was arrested and imprisoned (Nov. 858), and upon refusing to resign his office was illegally deposed, while Photius, although a layman, received all the necessary sacerdotal orders within six days, and was installed as patriarch in his place. Ignatius, continuing to refuse the abdication which could alone have given Photius's elevation a semblance of legality, was treated with extreme severity. His cause was subsequently espoused by Pope Nicholas in a manner highly offensive to the independent feeling of the Eastern Church. Photius felt himself the champion of Eastern Christianity against Latin pretensions; and when in 863 Nicholas finally anathematized and deposed him, he replied by a counter-excommunication. Meanwhile, the situation was suddenly changed by the murder of Photius's patron, Bardas, by order of the emperor Michael, who was himself assassinated by his colleague Basil in the following year (867). The fall of Photius immediately ensued; he was removed from his office and banished about the end of September 867, a few days after the accession of Basil, and Ignatius was reinstated on the 23rd of November. About 876 Photius was suddenly recalled to Constantinople and entrusted with the education of Basil's children. On the death of Ignatius, probably in October 878, Photius, after a decent show of reluctance, again filled the patriarchal throne. He then proceeded to obtain the formal recognition of the Christian world. In November 879 a synod was convened at Constantinople. The legates of Pope John VIII. attended, prepared to acknowledge Photius as legitimate patriarch, a concession for which John was much censured by Latin opinion. He stood firm, however, on the other two points which had long been contested between the Eastern and Western Churches, the ecclesiastical jurisdiction over Bulgaria and the introduction of the "filioque" clause into the creed. He disowned his legates, who had shown a tendency to yield, again excommunicated Photius, and thus aroused the open hostility which has never been appeased to this day. Strong in the support of the council, Photius simply ignored him. At the height of glory and success he was suddenly precipitated from his dignity by another palace revolution. After the death of Basil (886), his son and successor Leo, who had formerly been devoted to Photius, but in recent years displayed great hatred towards him, deprived him of his office and banished him to the monastery of Bordi in Armenia. From this time Photius disappears from history. No letters of this period of his life are extant, which leads to the inference that his imprisonment was severe. The precise date of his death is not known, but it is said to have occurred on the 6th of February 891.

For long after Photius's death his memory was held in no special honour by his countrymen. But when, in the crusading age, the Greek Church and state were alike in danger from Latin encroachments, Photius became a national hero, and is at present regarded as little short of a saint. To this character he has not the least pretension. Few men, it is probable, have been more atrociously calumniated; but, when every specific statement to his prejudice has been rejected, he still appears on a general review of his actions worldly, crafty and unscrupulous. Yet he shows to no little advantage as an ecclesiastical statesman. His firmness was heroic, his sagacity profound and farseeing; he supported good and evil fortune with equal dignity; and his fall was on both occasions due to revolutions beyond his control. In erudition, literary power, and force and versatility of intellect he far surpassed every contemporary.

The most important of the works of Photius is his renowned *Bibliotheca* or *Myriobiblon* (ed. I. Bekker, 1824–1825), a collection of extracts from and abridgments of 280 volumes of classical authors (usually cited as *Codices*), the originals of which are now to a great extent lost. The work is specially rich in extracts from historical writers. To Photius we are indebted for almost all we possess of Ctesias, Memnon, Conon, the lost books of Diodorus Siculus, and the lost writings of Arrian. Theology and ecclesiastical history are also very fully represented, but poetry and ancient philosophy are almost entirely ignored. It seems that he did not think it necessary to deal with those authors with whom every well-educated man would naturally be familiar. The literary criticisms, generally distinguished by keen and independent judgment, and the excerpts, vary considerably in length. The numerous biographical notices are probably taken from the work of Hesychius of Miletus. The *Lexicon* (Λέξεων Συναγωγή), published later than the *Bibliotheca*, was probably in the main the work of some of his pupils. It was intended as a book of reference to facilitate the reading of old classical and sacred authors, whose language and vocabulary were out of date. The only MS. of the *Lexicon* is the Codex Galeanus, formerly in the possession of Thomas Gale (*q.v.*), and now in the library of Trinity College, Cambridge (ed. S. A. Naber, 1864, with introduction on the authorities, critical commentary, and valuable indexes). His most important theological work is the *Amphilochia* a collection of some 300 questions and answers on difficult points in Scripture, addressed to Amphilochius, archbishop of Cyzicus (ed. Sophocles Oeconomus, Athens, 1858). Other similar works are his treatise in four books

against the Manichaeans and Paulicians, and his controversy with the Latins on the Procession of the Holy Spirit. His *Epistles*, political and private, addressed to high church and state dignitaries, are valuable for the light they throw upon the character and versatility of the writer (ed. J. Valettas, London, 1864). A large number of his speeches and homilies have been edited by S. Aristarches (1900). The only complete edition is Bishop Malou's in Migne's *Patrologia graeca*, ci.–cv. R. Reifzenstein (*Der Aufang des Lexikons des Photius*, 1907) has published a hitherto unedited MS. containing numerous fragments from various verse and prose authors.

After the allusions in his own writings the chief contemporary authority for the life of Photios is his bitter enemy, Nicetas the Paphlagonian, the biographer of his rival Ignatius. The standard modern work is that of Cardinal Hergenröther, *Photius, Patriarch von Constantinopel* (1867–1869). As a dignitary of the Roman Catholic Church, Cardinal Hergenröther is inevitably biased against Photius as an ecclesiastic, but his natural candour and sympathy with intellectual eminence have made him just to the man.

Fabricius, *Bibliotheca graeca*, x. 670–776, xi. 1–37; C. Krumbacher, *Geschichte der byzantinischen Litteratur*, pp. 73–79, 515–524 (2nd ed., 1897); J. E. Sandys, *History of Classical Scholarship* (2nd ed., 1906).

PHOTOCHEMISTRY (Gr. φῶς, light, and "chemistry"), in the widest sense, the branch of chemical science which deals with the optical properties of substances and their relations to chemical constitution and reactions; in the narrower sense it is concerned with the action of light on chemical change. The first definition includes such subjects as refractive and dispersive power, colour, fluorescence, phosphorescence, optical isomerism, spectroscopy, &c.—subjects which are treated under other headings; here we only discuss the subject matter of the narrower definition.

Probably the earliest photochemical investigations were associated with the darkening of certain silver salts under the action of light, processes which were subsequently utilized in photography (*q.v.*). At the same time, however, it had been observed that other chemical changes were regulated by the access of light; and the first complete study of such a problem was made by J. W. Draper in 1843, who investigated the combination of hydrogen and chlorine to form hydrochloric acid, a reaction which had been previously studied by Gay-Lussac and Thénard. Draper concluded that the first action of sunlight consisted in producing an allotrope of chlorine, which subsequently combined with the hydrogen. This was denied by Bunsen and Roscoe in 1857; and in 1887 Pringsheim suggested that the reaction proceeded in two stages: $H_2O+Cl_2=Cl_2O+H_2$, $2H_2+Cl_2O=H_2O+2HCl$. This view demands the presence of water vapour (H. B. Baker showed that the perfectly dry gases would not combine), and also explains the period which elapses before the reaction commenced (the "photochemical induction" of Bunsen and Roscoe) as taken up by the formation of the chlorine monoxide necessary to the second part of the reaction. The decomposition of hydriodic acid into hydrogen and iodine was studied by Lemoine in 1877, who found that 80 % decomposed after a month's exposure; he also observed that the reaction proceeded quicker in blue vessels than in red. A broader investigation was published by P. L. Chastaing in 1878, who found that the red rays generally oxidized inorganic compounds, whilst the violet reduces them, and that with organic compounds the action was entirely oxidizing. These and other reactions suggested the making of actinometers, or instruments for measuring the actinic effect of light waves. The most important employ silver salts; Eder developed a form based on the reaction between mercuric chloride and ammonium oxalate: $2HgCl_2+(NH_4)_2C_2O_4=2HgCl+2NH_4Cl+2CO_2$, the extent of the decomposition being determined by the amounts of mercurous chloride or carbon dioxide liberated.

The article PHOTOGRAPHY (*q.v.*) deals with early investigations on the chemical action of light, and we may proceed here to modern work on organic compounds. That sunlight accelerates the action of the halogens, chlorine and bromine, on such compounds, is well known. John Davy obtained phosgene, $COCl_2$, by the direct combination of chlorine and carbon monoxide in sunlight (see Weigert, *Ann. d. Phys.*, 1907 (iv.), 24, p. 55); chlorine combines with half its volume of methane explosively in sunlight, whilst in diffused light it substitutes; with toluene it gives benzyl chloride, $C_6H_5CH_2Cl$, in sunlight, and chlortoluene, $C_6H_4(CH)_3Cl$, in the dark; with benzene it gives an addition product, $C_6H_6Cl_6$, in sunlight, and substitutes in the dark. Bromine deports itself similarly, substituting and forming addition products with unsaturated compounds more readily in sunlight. Sometimes isomerization may occur; for instance, Wislicenus found that angelic acid gave dibromangelic acid in the dark, and dibromtiglic acid in sunlight. Many substances decompose when exposed to sunlight; for example, alkyl iodides darken, owing to the liberation of iodine; aliphatic acids (especially dibasic) in the presence of uranic oxide lose carbon dioxide; polyhydric alcohols give products identical with those produced by fermentation; whilst aliphatic ketones give a hydrocarbon and an acid.

Among aromatic compounds, benzaldehyde gives a trimeric and tetrameric benzaldehyde, benzoic acid and hydrobenzoin (G. L. Ciamician and P. Silber, *Atti. R. Accad. Lincei*, 1909); in alcoholic solution it gives hydrobenzoin; whilst with nitrobenzene it is oxidized to benzoic acid, the nitrobenzene suffering reduction to nitrosobenzene and phenyl-β-hydroxylamine; the latter isomerizes to ortho- and para-aminophenol, which, in turn, combine with the previously formed benzoic acid. Similarly acetophenone and benzophenone in alcoholic solution give dimethylhydrobenzoin and benzopinacone. With nitro compounds Sach and Hilbert concluded that those containing a ·CH· side group in the ortho position to the ·NO_2 group were decomposed by light. For example, ortho-nitrobenzaldehyde in alcoholic solution gives nitrosobenzoic ester and 22′ azoxybenzoic acid, with the intermediate formation of nitrobenzaldehyde-diethylacetal, $NO_2 \cdot C_6H_4 \cdot CH(OC_2H_5)_2$ (E. Bamberger and F. Elgar, *Ann.* 1910, 371, p. 319). Bamberger also investigated nitrosobenzene, obtaining azoxybenzene as chief product, together with various azo compounds, nitrobenzene, aniline, hydroquinone and a resin.

For the photochemistry of diazo derivatives see Roff and Stern, *Ber.*, 1901, 34, p. 1668, and of the terpenes see G. L. Ciamician and P. Silber, *Ber.*, 1907 and 1908.

Light is also powerful in producing isomerization and polymerization. Isomerization chiefly appears in the formation of stable stereo-isomers from the labile forms, and more rarely in inducing real isomerization or phototropy (Marckwald, 1899). As examples we may notice the observation of Chattaway (*Journ. Chem. Soc.* 1906, 89, p. 462) that many phenylhydrazones (yellow) change into azo compounds (red), of M. Padoa and F. Graziani (*Atti. R. Accad. Lincei*, 1909) on the β-naphthylhydrazones (the α-compounds are not phototropic), and of A. Senier and F. G. Shepheard (*Journ. Chem. Soc.*, 1909, 95, p. 1943) on the arylidene- and naphthylidene-amines, which change from yellow to orange on exposure to sunlight. Light need not act in the same direction as heat (changes due to heat may be termed *thermotropic*). For example, heat changes the α form of benzyl-β-aminocrotonic ester into the β form, whereas light reverses this; similarly heat and light have reverse actions with *as*-diphenyl ethylene, $CH_2:C(C_6H_5)_2$ (R. Stoermer, *Ber.*, 1909, 42, p. 4865); the change, however, is in the same direction with Senier and Shepheard's compounds. With regard to polymerization we may notice the production of benzene derivatives from acetylene and its homologues, and of tetramethylenes from the olefines.

Theory of Photochemical Action.—Although much work has been done in the qualitative and quantitative study of photochemical reactions, relatively little attention has been given to the theoretical explanation of these phenomena. That the solution was to be found in an analogy to electrolysis was suggested by Grotthuss in 1818, who laid down: (1) only those rays which are absorbed can produce chemical change, (2) the action of the light is analogous to that of a voltaic cell; and he regarded light as made up of positive and negative electricity. The first principle received early acceptance; but the development of the second is due to W. D. Bancroft who, in a series of

papers in the *Journal of Physical Chemistry* for 1908 and 1909, has applied it generally to the reactions under consideration. Any electrolytic action demands a certain minimum electromotive force; this, however, can be diminished by suitable depolarizers, which generally act by combining with a product of the decomposition. Similarly, in some photochemical reactions the low electromotive force of the light is sufficient to induce decomposition, but in other cases a depolarizer must be present. For example, ferric chloride in aqueous solution is unchanged by light, but in alcoholic solution reduction to ferrous chloride occurs, the liberated chlorine combining with the alcohol. In the same way Bancroft showed that the solvent media employed in photographic plates act as depolarizers. The same theory explains the action of sensitizers, which may act optically or chemically. In the first case they are substances having selective absorption, and hence alter the sensitivity of the system to certain rays. In the second case there are no strong absorption bands, and the substances act by combining with the decomposition products. Bancroft applied his theory to the explanation of photochemical oxidation, and also to the chlorination and bromination of hydrocarbons. In the latter case it is supposed that the halogen produces ions; if the positive ions are in excess side chains are substituted, if the negative the nucleus.

Standard treatises are: J. M. Eder, *Handbuch der Photographie*, vol. i. pt. 2 (1906); H. W. Vogel, *Photochemie* (1906). An account of the action of light on organic compounds is given in A. W. Stewart, *Recent Advances in Organic Chemistry* (1908).

PHOTOGRAPHY (Gr. φῶς, light, and γράφειν, to write), the science and art of producing pictures by the action of light on chemically prepared (sensitized) plates or films.

History.

It would be somewhat difficult to fix a date when what we now know as "photographic action" was first recorded. No doubt the tanning of the skin by the sun's rays was what was first noticed, and this is as truly the effect of solar radiation as is the darkening of the sensitive paper which is now in use in photographic printing operations. We may take it that K. W. Scheele was the first to investigate the darkening action of sunlight on silver chloride. He found that when silver chloride was exposed to the action of light beneath water there was dissolved in the fluid a substance which, on the addition of lunar caustic (silver nitrate), caused the precipitation of new silver chloride, and that on applying a solution of ammonia to the blackened chloride an insoluble residue of metallic silver was left behind. He also noticed that of the rays of the spectrum the violet most readily blackened the silver chloride. In Scheele, then, we have the first who applied combined chemical and spectrum analysis to the science of photography. In 1782 J. Senebier repeated Scheele's experiments, and found that in fifteen seconds the violet rays blackened silver chloride as much as the red rays did in twenty minutes.[1] In 1798 Count Rumford contributed a paper to the *Philosophical Transactions* entitled "An inquiry concerning the chemical properties that have been attributed to light," in which he tried to demonstrate that all effects produced on metallic solution could be brought about by a temperature somewhat less than that of boiling water. Robert Harrup in 1802, however, conclusively showed in *Nicholson's Journal* that, at all events, salts of mercury were reduced by visible radiation and not by change of temperature.

In 1801 we come to the next decided step in the study of photographic action, when Johann Wilhelm Ritter (1776–1810) proved the existence of rays lying beyond the violet, and found that they had the power of blackening silver chloride. Such a discovery naturally gave a direction to the investigations of others, and Thomas Johann Seebeck (1770–1831) (between 1802 and 1808) and, in 1812, Jacques Étienne Bérard (1789–1869) turned their attention to this particular subject, eliciting valuable information. We need only mention two or three other cases where the influence of light was noticed at the beginning of the 19th century. William Hyde Wollaston observed the conversion of yellow gum guaiacum into a green tint by the violet rays, and the restoration of the colour by the red rays—both of which are the effect of absorption of light, the original yellow colour of the gum absorbing the violet rays, whilst the green colour to which it is changed absorbs the red rays. Sir Humphry Davy found that puce-coloured lead oxide, when damp, became red in the red rays, whilst it blackened in the violet rays, and that the green mercury oxide became red in the red rays—again an example of the necessity of absorption to effect a molecular or chemical change in a substance. U. R. T. Le Bouvier Desmorties in 1801 observed the change effected in Prussian blue, and Carl Wilhelm Böckman noted the action of the two ends of the spectrum on phosphorus, a research which John William Draper extended farther in America at a later date.

To England belongs the honour of first producing a photograph by utilizing Scheele's observations on silver chloride. In June 1802 Thomas Wedgwood (1771–1805) published in the *Journal* of the Royal Institution the paper "An account of a method of copying paintings upon glass and of making profiles by the agency of light upon nitrate of silver, with observations by H. Davy." He remarks that white paper or white leather moistened with a solution of silver nitrate undergoes no change when kept in a dark place, but on being exposed to the daylight it speedily changes colour, and, after passing through various shades of grey and brown, becomes at length nearly black. The alteration of colour takes place more speedily in proportion as the light is more intense.

"In the direct beam of the sun two or three minutes are sufficient to produce the full effect, in the shade several hours are required, and light transmitted through different coloured glasses acts upon it with different degrees of intensity. Thus it is found that red rays, or the common sunbeams passed through red glass, have very little action upon it; yellow and green are more efficacious, but blue and violet light produce the most decided and powerful effects."

Wedgwood goes on to describe the method of using this prepared paper by throwing shadows on it, and inferentially by what we now call "contact printing." He states that he has been unable to fix his prints, no washing being sufficient to eliminate the traces of the silver salt which occupied the unexposed or shaded portions. Davy in a note states that he has found that, though the images formed by an ordinary camera obscura were too faint to print out in the solar microscope, the images of small objects could easily be copied on such paper.

"In comparing the effects produced by light upon muriate of silver (silver chloride) with those upon the nitrate it seemed evident that the muriate was the more susceptible, and both were more readily acted upon when moist than when dry—a fact long ago known. Even in the twilight the colour of the moist muriate of silver, spread upon paper, slowly changed from white to faint violet; though under similar circumstances no intermediate alteration was produced upon the nitrate. . . . Nothing but a method of preventing the unshaded parts of the delineations from being coloured by exposure to the day is wanting to render this process as useful as it is elegant."

In this method of preparing the paper lies the germ of the silver-printing processes of modern times, and it was only by the spread of chemical knowledge that the hiatus which was to render the "process as useful as it is elegant" was filled up—when sodium thiosulphate (hyposulphite of soda), discovered by François Chaussier in 1799, or three years before Wedgwood published his paper, was used for making the print permanent. Here we must call attention to an important observation by Seebeck of Jena in 1810. In the *Farbenlehre* of Goethe he says:—

"When a spectrum produced by a properly constructed prism is thrown upon moist chloride of silver paper, if the printing be continued for from fifteen to twenty minutes, whilst a constant position for the spectrum is maintained by any means, I observe the following. In the violet the chloride is a reddish brown (sometimes more violet, sometimes more blue), and this coloration extends well beyond the limit of the violet; in the blue the chloride takes a clear blue tint, which fades away, becoming lighter in the green. In the yellow I usually found the chloride unaltered; sometimes, however, it had a light yellow tint; in the red and beyond the red it took a rose or lilac tint. This image of the spectrum shows beyond the red and the violet a region more or less light and uncoloured. This is how the decomposition of the silver chloride is seen in this region. Beyond

[1] It may here be remarked that had he used a pure spectrum he would have found that the red rays did not blacken the material in the slightest degree.

the brown band, . . . which was produced in the violet, the silver chloride was coloured a grey-violet for a distance of several inches. In proportion as the distance from the violet increased, the tint became lighter. Beyond the red, on the contrary, the chloride took a feeble red tint for a considerable distance. When moist chloride of silver, having received the action of light for a time, is exposed to the spectrum, the blue and violet behave as above. In the yellow and red regions, on the other hand, it is found that the silver chloride becomes paler; . . . the parts acted upon by the red rays and by those beyond take a light coloration."

This has been brought forward by J. M. Eder as being the first record we have of photographic action lending itself to production of natural colours. This observation of Seebeck was allowed to lie fallow for many years, until it was again taken up and published as a novelty.

The first to found a process of photography which gave pictures that were subsequently unaffected by light was Nicéphore de Niepce. His process, which he called provisionally "héliographie, dessins, et gravures," consists in coating the surface of a metallic plate with a solution of asphaltum in oil of lavender and exposing it to a camera image. He recommends that the asphaltum be powdered and the oil of lavender dropped upon it in a wine-glass, and that it be then gently heated. A polished plate is covered with this varnish, and, when dried, is ready for employment in the camera. After requisite exposure, which is very long indeed, a very faint image, requiring development, is seen. Development is effected by diluting oil of lavender with ten parts by volume of white petroleum. After this mixture has been allowed to stand two or three days it becomes clear and is ready to be used. The plate is placed in a dish and covered with the solvent. By degrees the parts unaffected by light dissolve away, and the picture, formed of modified asphaltum, is developed. The plate is then lifted from the dish, allowed to drain, and finally freed from the remaining solvents by washing in water. Subsequently, instead of using oil of lavender as the asphaltum solvent, Niepce employed an animal oil, which gave a deeper colour and more tenacity to the surface-film.

Later, Louis Jacques Mandé Daguerre (1789–1851) and Niepce used as a solvent the brittle residue obtained from evaporating the oil of lavender dissolved in ether or alcohol a transparent solution of a lemon-yellow colour being formed. This solution was used for covering glass or silver plates, which, when dried, could be used in the camera. The time of exposure varied somewhat in length. Daguerre remarked that "the time required to procure a photographic copy of a landscape is from seven to eight hours, but single monuments, when strongly lighted by the sun, or which are themselves very bright, can be taken in about three hours." Perhaps there is no sentence that illustrates more forcibly the advance made in photography from the days when this process was described. The ratio of three hours to $\frac{1}{250}$th of a second is a fair estimate of the progress made since Niepce. The development was conducted by means of petroleum-vapour, which dissolved the parts not acted upon by light. As a rule silver plates seem to have been used, and occasionally glass; but it does not appear whether the latter material was chosen because an image would be projected through it or whether simply for the sake of effect. Viewed in the light of present knowledge, a more perfectly developable image in half-tone would be obtained by exposing the film through the *back* of the glass. The action of light on most organic matter is apparently one of oxidation. In the case of asphaltum or bitumen of Judaea the oxidation causes a hardening of the material and an insolubility in the usual solvents. Hence that surface of the film is generally hardened first which first feels the influence of light. Where half-tones exist, as in a landscape picture, the film remote from the surface first receiving the image is not acted upon at all, and remains soluble in the solvent. It is thus readily seen that, in the case of half-tone pictures, or even in copying engravings, if the action were not continued sufficiently long when the surface of the film farthest from the glass was first acted upon, the layer next the glass would in some places remain soluble, and on development would be dissolved away, carrying the top layer of hardened resinous matter with it, and thus give rise to imperfect pictures. In carbon-printing development from the back of the exposed film is absolutely essential, since it depends on the same principles as does heliography, and in this the same mode of procedure is advisable.

It would appear that Niepce began his researches as early as 1814, but it was not till 1827 that he had any success worth recounting. At that date he communicated a paper to Dr Bauer of Kew, the secretary of the Royal Society of London, with a view to its presentation to that society. Its publication, however, was prevented because the process, of which examples were shown, was a secret one. In an authentic MS. copy of Niepce's "Mémoire," dated "Kew, le 8 Décembre 1827," he says that "in his framed drawings made on tin the tone is too feeble, but that by the use of chemical agents the tone may be darkened." This shows that Niepce was familiar with the idea of using some darkening medium even with his photographs taken on tin plates.

Daguerreotype.—We have noticed in the joint process of Daguerre and Niepce that polished silver plates were used, and we know from the latter that amongst the chemical agents tried iodine suggested itself. Iodine vapour or solution applied to a silvered plate would cause the formation of silver iodide on those parts not acted upon by light. The removal of the resinous picture would leave an image formed of metallic silver, whilst the black parts of the original would be represented by the darker silver iodide. This was probably the origin of the daguerreotype process. Such observers as Niepce and Daguerre, who had formed a partnership for prosecuting their researches, would not have thus formed silver iodide without noticing that it changed in colour when exposed to the light. What parts respectively Daguerre and Niepce played in the development of the daguerreotype will probably never be known with absolute accuracy, but in a letter from Dr Bauer to Dr J. J. Bennett, F.R.S., dated the 7th of May 1839, the former says:—

"I received a very interesting letter from Mons. Isidore Niepce, dated 12th March [about a month after the publication of the daguerreotype process], and that letter fully confirms what I suspected of Daguerre's manœuvres with poor Nicéphore, but Mr Isidore observes that for the present that letter might be considered confidential."

Dr Bauer evidently knew more of "poor Nicéphore's" work than most people, and at that early period he clearly thought that an injustice had been done to Niepce at the hands of Daguerre. It should be remarked that Nicéphore de Niepce died in 1833, and a new agreement was entered into between his son Isidore de Niepce and Daguerre to continue the prosecution of their researches. It appears further that Niepce communicated his process to Daguerre on the 5th of December 1829. At his death some letters from Daguerre and others were left by him in which iodine, sulphur, phosphorus, &c., are mentioned as having been used on the metal plates, and their sensitiveness to light, when thus treated, commented upon. We are thus led to believe that a great part of the success in producing the daguerreotype is due to the elder Niepce; and indeed it must have been thought so at the time, since, on the publication of the process, life-pensions of 6000 francs and 4000 francs were given to Daguerre and to Isidore Niepce respectively. In point of chronology the publication of the discovery of the daguerreotype process was made subsequently to the Talbotype process. It will, however, be convenient to continue the history of the daguerreotype, premising that it was published on the 6th of February 1839, whilst Talbot's process was given to the world on the 25th of January of the same year.

Daguerreotype pictures were originally taken on silver-plated copper, and even now the silvered surface thus prepared serves better than electro-deposited silver of any thickness. An outline of the operations is as follows. A brightly polished silver plate is cleaned by finely powdered pumice and olive oil, and then by dilute nitric acid, and a soft buff is employed to give it a brilliant polish, the slightest trace of foreign matter or stain being fatal to the production of a perfect picture. The plate, thus prepared, is ready for the iodizing operation. Small fragments of iodine are scattered over a saucer, covered with gauze. Over this the plate is placed, face downwards, resting on supports, and the vapour from the iodine is allowed to form upon it a surface of silver iodide. It is essential to note the colour of the surface-formed iodide at its several stages, the varying colours being due to interference colours

caused by the different thicknesses of the minutely thin film of iodide. The stage of maximum sensitiveness is obtained when it is of a golden orange colour. In this state the plate is withdrawn and removed to the dark slide of the camera, ready for exposure. A plan frequently adopted to give an even film of iodide was to saturate a card with iodine and hold the plate a short distance above the card. Long exposures were required, varying in Paris from three to thirty minutes. The length of the exposure was evidently a matter of judgment, more particularly as over-exposure introduced an evil which was called "solarization," but which was in reality due to the oxidation of the iodide by prolonged exposure to light.

As a matter of history it may be remarked that the development of the image by mercury vapour is said to be due to a chance discovery of Daguerre. It appears that for some time previous to the publication of the daguerreotype method he had been experimenting with iodized silver plates, producing images by what would now be called the "printing out" process. This operation involved so long an exposure that he sought some means of reducing it by the application of different reagents. Having on one occasion exposed such a plate to a camera-image, he accidentally placed it in the dark in a cupboard containing various chemicals, and found after the lapse of a night that he had a perfect image developed. By the process of exhaustion he arrived at the fact that it was the mercury vapour, which even at ordinary temperatures volatilizes, that had caused this intensification of the almost invisible camera-image. It was this discovery that enabled the exposures to be very considerably shortened from those which it was found necessary to give in mere camera-*printing*.

The development of the image was effected by placing the exposed plate over a slightly heated (about 75° C.) cup of mercury. The vapour of mercury condensed on those places where the light had acted in an almost exact ratio to the intensity of its action. This produced a picture in an amalgam, the vapour of which attached itself to the altered silver iodide. Proof that such was the case was subsequently afforded by the fact that the mercurial image could be removed by heat. The developing box was so constructed that it was possible to examine the picture through a yellow glass window whilst the image was being brought out. The next operation was to fix the picture by dipping it in a solution of hyposulphite of soda. The image produced by this method is so delicate that it will not bear the slightest handling, and has to be protected from accidental touching.

The first great improvement in the daguerreotype process was the resensitizing of the iodized film by bromine vapour. John Frederick Goddard published his account of the use of bromine in conjunction with iodine in 1840, and A. F. J. Claudet (1797–1867) employed a combination of iodine and chlorine vapour in 1841. In 1844 Daguerre published his improved method of preparing the plates, which is in reality based on the use of bromine with iodine. That this addition points to additional sensitiveness will be readily understood when we remark that so-called instantaneous pictures of yachts in full sail, and of large size, have been taken on plates so prepared—a feat which is utterly impossible with the original process as described by Daguerre. The next improvement in the process was toning or gilding the image by a solution of gold, a practice introduced by H. L. Fizeau. Gold chloride is mixed with hyposulphite of soda, and the levelled plate, bearing a sufficient quantity of the fluid, is warmed by a spirit-lamp until the required vigour is given to the image, as a consequence of which it is better seen in most lights. Nearly all the daguerreotypes extant have been treated in this manner, and no doubt their permanence is in a great measure due to this operation. Images of this class can be copied by taking electrotypes from them, as shown by Sir W. R. Grove and others. These reproductions are admirable in every way, and furnish a proof that the daguerrean image is a relief.

Fox-Talbot Process.—In January 1839 Fox Talbot described the first of his processes, photogenic drawing, in a paper to the Royal Society. He states that he began experimenting in 1834, and that in the solar microscope he obtained an outline of the object to be depicted in full sunshine in half a second. He published in the *Philosophical Magazine* full details of his method, which consisted essentially in soaking paper in common salt, brushing one side only of it with about a 12 % solution of silver nitrate in water, and drying at the fire. Fox Talbot stated that by repeating the alternate washes of the silver and salt—always ending, however, with the former—greater sensitiveness was attained. This is the same in every respect as the method practised by Wedgwood in 1802; but, when we come to the next process, which he called "calotype" or "beautiful picture," we have a distinct advance. This process Talbot protected by a patent in 1841.

It may be briefly described as the application of silver iodide to a paper support. Carefully selected paper was brushed over with a solution of silver nitrate (100 grains to the ounce of distilled water), and dried by the fire. It was then dipped into a solution of potassium iodide (500 grains being dissolved in a pint of water), where it was allowed to stay two or three minutes until silver iodide was formed. In this state the iodide is scarcely sensitive to light, but is sensitized by brushing "gallo-nitrate of silver" over the surface to which the silver nitrate had been first applied. This "gallo-nitrate" is merely a mixture, consisting of 100 grains of silver nitrate dissolved in 2 oz. of water, to which is added one-sixth of its volume of acetic acid, and immediately before applying to the paper an equal bulk of a saturated solution of gallic acid in water. The prepared surface is then ready for exposure in the camera, and, after a short insolation, develops itself in the dark, or the development may be hastened by a fresh application of the "gallo-nitrate of silver." The picture is then fixed by washing it in clean water and drying slightly in blotting paper, after which it is treated with a solution of potassium bromide, and again washed and dried. Here there is no mention made of hyposulphite of soda as a fixing agent, that having been first used by Sir J. Herschel in February 1840.

In a strictly historical notice it ought to be mentioned that development by means of gallic acid and silver nitrate was first known to Rev. J. B. Reade. When impressing images in the solar microscope he employed gallic acid and silver in order to render more sensitive the silver chloride paper that he was using, and he accidentally found that the image could be developed without the aid of light. The priority of the discovery was claimed by Fox Talbot; and his claim was sustained after a lawsuit, apparently on the ground that Reade's method had never been legally published. Talbot afterwards made many slight improvements in the process. In one of his patents he recognizes the value of the proper fixing of his photogenic drawings by hyposulphite of soda, and also the production of positive prints from the calotype negatives. We pass over his application of albumen to porcelain and its subsequent treatment with iodine vapour, as also his application of albumen in which silver iodide was held in suspension to a glass plate, since in this he was preceded by Niepce de St Victor in 1848.

Albumen Process on Glass.—It was a decided advance when Niepce de St Victor, a nephew of Nicéphore de Niepce, employed a glass plate and coated it with iodized albumen. The originator of this method did not meet with much success. In the hands of Blanquart Évrard it became more practicable; but it was carried out in its greatest perfection by G. Le Gray.

The outline of the operations is as follows. The whites of five fresh eggs are mixed with about one hundred grains of potassium iodide, about twenty grains of potassium bromide and ten grains of common salt. The mixture is beaten up into a froth and allowed to settle for twenty-four hours, when the clear liquid is decanted off. A circular pool of albumen is poured on a glass plate, and a straight ruler (its ends being wrapped with waxed paper to prevent its edge from touching the plate anywhere except at the margins) is drawn over the plate, sweeping off the excess of albumen, and so leaving an even film. The plate is first allowed to dry spontaneously, a final heating being given to it in an oven or before the fire. The heat hardens the albumen, and it becomes insoluble and ready for the silver nitrate bath. One of the difficulties is to prevent crystallization of the salts held in solution, and this can only be effected by keeping them in defect rather than in excess. The plate is sensitized for five minutes in a bath of silver nitrate, acidified with acetic acid, and exposed whilst still wet, or it may be slightly washed and again dried and exposed whilst in its desiccated state. The image is developed by gallic acid in the usual way.

After the application of albumen many modifications were introduced in the shape of starch, serum of milk, gelatin, all of which were intended to hold iodide *in situ* on the plate; and the development in every case seems to have been by gallic acid. At one time the waxed-paper process subsequently introduced by Le Gray was a great favourite. Paper that had been made translucent by white wax was immersed in a solution of potassium iodide until impregnated with it, after which it was sensitized in the usual way, development being by gallic acid. In images obtained by this process the high lights are represented by metallic silver, whilst the shadows are translucent. Such a print is called a "negative." When silver chloride paper is darkened by the passage of light through a negative, we get the highest lights represented by white paper and the shadows by darkened chloride. A print of this kind is called a "positive."

Collodion Process.—A great impetus was given to photography

in 1850, on the introduction of collodion (*q.v.*), a very convenient vehicle on account of the facility with which the plates are prepared, and also because it is a substance as a rule totally unaffected by silver nitrate, which is not the case with other organic substances. Thus albumen forms a definite silver compound, as do gelatin, starch and gum. The employment of collodion was first suggested by Le Gray, but it remained for Frederick Scott Archer of London, closely followed by P. W. Fry, to make a really practical use of the discovery. When collodion is poured on a glass plate it leaves on drying a hard transparent film which under the microscope is slightly reticulated. Before drying, the film is gelatinous and perfectly adapted for holding *in situ* salts soluble in ether and alcohol. Where such salts are present they crystallize out when the film is dried, hence such a film is only suitable where the plates are ready to be immersed in the silver bath. As a rule, about five grains of the soluble gun-cotton are dissolved in an ounce of a mixture of equal parts of ether and alcohol, both of which must be of low specific gravity, ·725 and ·805 respectively. If the alcohol or ether be much diluted with water the gun-cotton (pyroxylin) precipitates, but, even if less diluted, it forms a film which is "crapey" and uneven. Such was the material which Le Gray proposed and which Archer brought into practical use. The opaque silver plate with its one impression was abandoned; and the paper support of Talbot, with its inequalities of grain and thickness, followed suit, though not immediately. When once a negative had been obtained with collodion on a glass plate—the image showing high lights by almost complete opacity and the shadows by transparency (as was the case, too, in the calotype process)—any number of impressions could be obtained by means of the silver-printing process introduced by Fox Talbot, and they were found to possess a delicacy and refinement of detail that certainly eclipsed the finest print obtained from a calotype negative. To any one who had practised the somewhat tedious calotype process, or the waxed-paper process of Le Gray with its still longer preparation and development, the advent of the collodion method must have been extremely welcome, since it effected a saving in time, money and uncertainty. The rapidity of photographic action was much increased, and the production of a different character of pictures thus became possible.

We give an outline of the procedure. A glass plate is carefully cleaned by a detergent such as a cream of tripoli powder and spirits of wine (to which a little ammonia is often added), then wiped with a soft rag, and finally polished with a silk handkerchief or chamois leather. A collodion containing soluble iodides and bromides is made to flow over the plate, all excess being drained off when it is covered. A good standard formula for the collodion is—55 grains of pyroxylin, 5 oz. of alcohol, 5 oz. of ether; and in this liquid are dissolved 2½ grains of ammonium iodide, 2 grains of cadmium iodide and 2 grains of cadmium bromide. When the collodion is set the plate is immersed in a bath of silver nitrate—a vertical form being that mostly used in England, whilst a horizontal dish is used on the continent of Europe—a good formula for which is 350 grains of silver nitrate with 10 oz. of water. The plate is steadily lowered into this solution, and moved in it until all the repellent action between the aqueous solution of the silver and the solvents of the collodion is removed, when it is allowed to rest for a couple of minutes, after which period it is taken out and placed in the dark slide ready for exposure in the camera. After undergoing proper exposure the plate is withdrawn, and in a room lighted with yellow light the developing solution is applied, which originally was a solution of pyrogallic acid in water restrained in its action by the addition of acetic acid. One of the old formulae employed by P. H. Delamotte was 9 grains of pyrogallic acid, 2 drachms of glacial acetic acid and 3 oz. of water. The image gradually appears after the application of this solution, building itself up from the silver nitrate clinging to the film, which is reduced to the metallic state by degrees. Should the density be insufficient a few drops of silver nitrate are added to the pyrogallic acid solution and the developing action continued.

In 1844 Robert Hunt introduced another reducing agent, which is still the favourite, viz. ferrous sulphate. By its use the time of necessary exposure of the plate is reduced and the image develops with great rapidity. A [illegible] of this developing solution is 20 grains of ferrous sulphate, [illegible] minims of acetic acid, with 1 oz. of water. This often leaves the image thinner than is requisite for the formation of a good print, and it is intensified with pyrogallic acid and silver. Other intensifiers are used to increase the deposit on a plate by means of mercury or uranium, followed by other solutions to still further darken the double salts formed on the film. Such intensifying agents have to be applied to the image after the plate is fixed, which is done by a concentrated solution of hyposulphite of soda or by potassium cyanide, the latter salt having been first introduced by Martin and Marc Antoine Augustin Gaudin in 1853 (*La Lumière*, April 23, 1853). Twenty-five grains of potassium cyanide to one ounce of water is the strength of the solution usually employed. The reaction of both these fixing agents is to form with the sensitive salts of silver double hyposulphites or cyanides, which are soluble in water and salt. The utility of bromides in the collodion process seems to have been recognized in its earliest days, Scott Archer (1852) and R. J. Bingham (1850) both mentioning it. We notice this, since as late as 1860 a patent-right in its use was sought to be enforced in America, the patent being taken out by James Cutting in July 1854.

Positive Pictures by the Collodion Process.—In the infancy of the collodion process it was shown by Horne that a negative image could be made to assume the appearance of a positive by whitening the metallic silver deposit. This he effected by using with the pyrogallic acid developer a small quantity of nitric acid. A better result was obtained by P. W. Fry with ferrous sulphate and ferrous nitrate, whilst Hugh Diamond gave effect to the matter in a practical way. F. Scott Archer used mercuric chloride to whiten the image. To Robert Hunt, however, must be awarded the credit of noticing the action of this salt on the image (*Phil. Trans.*, 1843). The whitened picture may be made to stand out against black velvet, or black varnish may be poured over the film to give the necessary black background, or, more recently, the positive pictures may be produced on japanned iron plates (ferrotype plates) or on japanned leather. This process is still occasionally practised by itinerant photographers.

Moist Collodion Process.—It is seen that for the successful working of the collodion process it was necessary that the plate should be exposed very shortly after its preparation; this was a drawback, inasmuch as it necessitated taking a heavy equipment into the field. In 1856, Sir William Crookes and J. Spiller published in the *Philosophical Magazine* a process whereby they were enabled to keep a film moist (so as to prevent crystallization of the silver nitrate) several days, enabling plates to be prepared at home, exposed in the field, and then developed in the dark room. The plate was prepared in the usual way and a solution of zinc nitrate and silver nitrate in water was made to flow over it. The hygroscopic nature of the zinc salt kept sufficient moisture on the plate to attain the desired end. Various modifications in procedure have been made.

Dry Plates.—It would appear that the first experiments with collodion dry plates were due to Marc Antoine Augustin Gaudin. In *La Lumière* of the 22nd of April and the 27th of May 1854 he describes his researches on the question; whilst in England G. R. Muirhead, on the 4th of August 1854, stated that light acts almost as energetically on a dry surface as on a wet after all the silver has been washed away from the former previous to desiccation. J. M. Taupenot, however, seems to have been the first to use a dry-plate process that was really workable. His original plan was to coat a plate with collodion, sensitize it in the ordinary manner, wash it, cause a solution of albumen to flow over the surface, dry it, dip it in a bath of silver nitrate acidified with acetic acid, and wash and dry it again. The plate was then in a condition to be exposed, and was to be developed with pyrogallic acid and silver. In this method we have a double manipulation, which is long in execution, though perfectly effective.

A great advance was made in all dry-plate processes by the introduction of what is known as the "alkaline developer," which is, however, inapplicable to all plates on which silver nitrate is present in the free state. The developers previously described, either for collodion or paper processes, were dependent on the reduction of metallic silver by some such agent as ferrous sulphate, the reduction taking place gradually and the reduced particles aggregating on those portions of the film which had been acted upon by light. The action of light being to reduce the silver iodide, bromide or chloride, these reduced particles really acted as nuclei for the crystallized metal. It will be evident that in such a method of development the molecular attraction

acts at distances relatively great compared with the diameters of the molecules themselves. If it were possible to reduce the altered particles of silver salt it was plain that development would be more rapid, and also that the number of molecules reduced by light would be smaller if the metallic silver could be derived from silver compounds within shorter distances of the centres of molecular attraction. Alkaline development accomplished this to a very remarkable extent; but the method is only really practicable when applied to films containing silver bromide and chloride, as silver iodide is only slightly amenable to the alkaline development. The introduction of this developer is believed to be of American origin; and it is known that in the year 1862 Major C. Russell used it with the dry plates he introduced.

An alkaline developer consists of an alkali, a reducing agent and a restraining agent. These bodies, when combined and applied to the solid silver bromide or chloride, after being acted upon by light, were able to reduce the sub-bromide or sub-chloride, and to build up an image upon it, leaving the unaltered bromide intact, except so far as it was used in the building up. In 1877 Sir W. Abney investigated this action. A dry plate was prepared by the bath process in the usual manner (to be described below), and exposed in the camera. The exposed film was covered with another film of collodiobromide emulsion, which of course had not seen the light. An image was obtained from the double film by means of the alkaline developer, which penetrated through the upper unexposed film. The development was prolonged until an image appeared through the unexposed film, when the plate was fixed, washed and dried. A piece of gelatinous paper was cemented on the upper film, and a similar piece on the lower after both had been stripped off the glass. When quite dry the two papers were forcibly separated, a film adhering to each. The upper film, *although never exposed to light*, showed an image in some cases more intense than the under film. The action of the alkaline developer was here manifest: the silver bromide in close contiguity to the exposed particles was reduced to the metallic state. Hence, from this and similar experiments, Abney concluded that silver bromide could not exist in the presence of a freshly precipitated or reduced metallic silver, and that a sub-bromide was immediately formed. From this it will be seen that the deposited silver is well within the sphere of molecular attraction, and that consequently a less exposure (*i.e.* the reduction of fewer molecules of the sensitive salt) would give a developable image.

The alkalis used embraced the alkalis themselves and the mono-carbonates. The sole reducing agent up till recent times was pyrogallic acid. In the year 1880 Abney found that hydroquinone was even more effective than pyrogallic acid, its reducing power being stronger. Various other experimentalists tried other kindred substances, but without adding to the list of really useful agents until recently.

The following are some of the most effective:—

Eikonogen Developer.

Eikonogen	25 parts.
Sodium sulphite	50 ,,
Sodium carbonate	50 ,,
Potassium bromide	½ ,,
Water	1000 ,,

This is a one-solution developer, and acts energetically.

Metol Developer.

Solution A.

Metol	2 parts.
Sodium sulphite	18 ,,
Water	100 ,,

Solution B.

Sodium carbonate	6 parts.
Potassium bromide	1 ,,
Water	100 ,,

For use, take one part of A to from 1 to 3 parts of B.

Amidol Developer.

Amidol	3 parts.
Sodium sulphite	100 ,,
Potassium bromide	1 to 3 ,,
Water	1000 ,,

This developer requires no addition of alkali.

Ortol Developer.

Solution A.

Ortol	15 parts.
Sodium metabisulphite	7 ,,
Water	1000 ,,

Solution B.

Sodium carbonate	100 parts.
Sodium sulphite	125
Potassium bromide	3 ,,
Water	1000 ,,

A and B solutions are mixed together in equal proportions.

Besides these, there are several more, such as adurol, glycin, pyrocatechin, which have been used with more or less success. They all give a black in lieu of that dark olive-green deposit of silver which is so often found with pyrogallol developers. All are alkaline developers, and the image is built up from the sensitive salt within the film. They are applicable to gelatin or collodion plates, but for the latter rather more bromide of an alkali is added, to retard fogging.

Another set of developers for dry plates dependent on the reduction of the silver bromide and the metallic state is founded on the fact that certain organic salts of iron can be utilized. In 1877 M. Carey Lea of Philadelphia and William Willis announced almost simultaneously that a solution of ferrous oxalate in neutral potassium oxalate was effective as a developer, and from that time its use has been acknowledged. In 1882 J. M. Eder demonstrated that gelatino-silver chloride plates could be developed with ferrous citrate, which could not be so readily accomplished with ferrous oxalate. The exposure for chloride plates when developed by the latter was extremely prolonged. In the same year Abney showed that if ferrous oxalate were dissolved in potassium citrate a much more powerful agent was formed, which allowed not only gelatino-chloride plates to be readily developed but also collodio-chloride plates. These plates were undevelopable except by the precipitation method until the advent of the agents last-mentioned owing to the fact that the chloride was as readily reduced as the sub-chloride.

Amongst the components of an alkaline developer we mentioned a restrainer. This factor, generally a bromide or chloride of an alkali, serves probably to form a compound with the silver salt which has not been acted upon by light, and which is less easily reduced than is the silver salt alone—the altered particles being left intact. The action of the restrainer is regarded by some as due to its combination with the alkali. But whichever theory is correct the fact remains that the restrainer does make the primitive salt less amenable to reduction. Such restrainers as the bromides of the alkalis act through chemical means; but there are others which act through physical means, an example of which we have in the preparation of a gelatin plate. In this case the gelatin wraps up the particles of the silver compound in a colloidal sheath, as it were, and the developing solution only gets at them in a very gradual manner, for the natural tendency of all such reducing agents is to attack the particles on which least work has to be expended. In the case of silver sub-bromide the developer has only to remove one atom of bromine, whereas it has to remove two in the case of silver bromide. The sub-bromide formed by light and that subsequently produced in the act of development are therefore reduced. A large proportion of gelatin compared with the silver salt in a film enables an alkaline developer to be used without any chemical restrainer; but when the gelatin bears a small proportion to the silver such a restrainer has to be used. With collodion films the particles of bromide are more or less unenveloped, and hence in this case some kind of chemical restrainer is absolutely necessary. We may say that the organic iron developers require less restraining in their action than do the alkaline developers.

In Major Russell's process the plate was prepared by immersion in a strong solution of silver nitrate and then washed and a preservative applied. The last-named agent executes two functions, one being to absorb the halogen liberated by the action of light and the other to preserve the film from atmospheric action. Tannin, which Major Russell employed, if we mistake not, is a good absorbent of the halogens, and acts as a varnish to the film. Other collodion dry-plate processes carried out by means of the silver-nitrate bath were very numerous at one time, many different organic bodies being also employed. In most cases ordinary iodized collodion was made use of, a small percentage of soluble bromide being as a rule added to it. When plates were developed by the alkaline method this extra bromide induced density, since it was the silver bromide alone which was amenable to it, the iodide being almost entirely unaffected by the weak developer which was at that time in general use.

Dry-Plate Bath Process.—One of the most successful bath dry-plate processes was introduced by R. Manners Gordon. The plate was given an edging of albumen and then coated with ordinary iodized collodion to which one grain per ounce of cadmium bromide had been added. It was kept in the silver-nitrate bath for ten minutes, after which it was washed thoroughly. The following preservative was then applied:—

1.	Gum arabic	20 grs.
	Sugar candy	5 ,,
	Water	6 dr.
2	Gallic acid	3 grs.
	Water	2 dr.

These ingredients were mixed just before use and, after filtering, applied for one minute to the plate, which was allowed to drain and set up to dry naturally. Great latitude is admissible in the exposure; it should rarely be less than four times or more than twenty times that which would be required for a wet plate under ordinary circumstances. The image may be developed with ferrous sulphate restrained by a solution of gelatin and glacial acetic acid, to which a solution of silver nitrate is added just before application, or by an alkaline developer.

In photographic processes not only has the chemical condition of the film to be taken into account but also the optical. When light falls on a semi-opaque or translucent film it is scattered by the particles in it and passes through the glass plate to the back. Here the rays are partly transmitted and partly reflected, a very small quantity of them being absorbed by the material of the glass. Theory points out that the strongest reflection from the back of the glass should take place at the "critical" angle. In 1875 Abney investigated the subject and proved that practice agreed with theory in every respect, and that the image of a point of light in development on a plate was surrounded by a ring of reduced silver caused by the reflection of the scattered light from the back surface of the glass, and that this ring was shaded inwards and outwards in such a manner that the shading varied with the intensity of the light reflected at different angles. To avoid "halation," as this phenomenon is called, it was usual to cover the back of dry plates with some material which should be in optical contact with it, and as nearly as possible of the same density as glass, and which at the same time should absorb all the photographically active rays. This was called "backing a plate."

Collodion Emulsion Processes.—In 1864 W. B. Bolton and B. J. Sayce published the germ of a process which revolutionized photographic manipulations. In the ordinary collodion process a sensitive film is procured by coating a glass plate with collodion containing the iodide and bromide of some soluble salt, and then, when set, immersing it in a solution of silver nitrate in order to form silver iodide and bromide in the film. The question that presented itself to Bolton and Sayce was whether it might not be possible to get the sensitive salts of silver formed *in* the collodion whilst liquid, and a sensitive film given to a plate by merely letting this collodion, containing the salts in suspension, flow over the glass plate. Gaudin had attempted to do this with silver chloride, and later G. W. Simpson had succeeded in perfecting a printing process with collodion containing silver chloride, citric acid and silver nitrate; but the chloride until recently has been considered a slow working salt, and nearly incapable of development. Up to the time of W. B. Bolton and B. J. Sayce's experiments silver iodide had been considered the staple of a sensitive film on which to take negatives; and though bromide had been used by Major Russell and others, it had not met with so much favour as to lead to the omission of the iodide. At the date mentioned the suspension of silver iodide in collodion was not thought practicable, and the inventors of the process turned their attention to silver bromide, which they found could be secured in such a fine state of division that it remained suspended for a considerable time in collodion, and even when precipitated could be resuspended by simple agitation. The outline of the method was to dissolve a soluble bromide in plain collodion, and add to it drop by drop an alcoholic solution of silver nitrate, the latter being in excess or defect according to the will of the operator. To prepare a sensitive surface the collodion containing the emulsified sensitive salt was poured over a glass plate, allowed to set, and washed till all the soluble salts resulting from the double decomposition of the soluble bromide and the silver nitrate, together with the unaltered soluble bromide or silver nitrate, were removed, when the film was exposed wet, or allowed to dry and then exposed. The rapidity of these plates was not in any way remarkable, but the process had the great advantage of doing away with the sensitizing nitrate of silver bath, and thus avoiding a tiresome operation. The plates were developed by the alkaline method, and gave images which, if not primarily dense enough, could be intensified by the application of pyrogallic acid and silver nitrate as in the wet collodion process. Such was the crude germ of a method which was destined to effect a complete change in the aspect of photographic negative taking [1]; but for some time it lay dormant. In fact there was at first much to discourage trial of it, since the plates often became veiled on development.

M Carey Lea of Philadelphia, and W. Cooper, jun., of Reading, may be said to have given the real impetus to the method. Carey Lea, by introducing an acid into the emulsion, established a practicable collodion emulsion process, which was rapid and at the same time gave negative pictures free from veil. To secure the rapidity Carey Lea employed a fair excess of silver nitrate, and Colonel H. Stuart Wortley gained further rapidity by a still greater increase of it; the free use of acid was the only means by which this could be effected without hopelessly spoiling the emulsion. The addition of the mineral acids such as Carey Lea employed is to prevent the formation of (or to destroy when formed) any silver sub-bromide or oxide, either of which acts as a nucleus on which development can take place. Abney first showed the theoretical effect of acids on the sub-bromide, as also the effect of oxidizing agents on both the above compounds (see below). A more valuable modification was introduced in 1874 by W. B. Bolton, one of the originators of the process, who allowed the ether and the alcohol of the collodion to evaporate, and then washed away all the soluble salts from the gelatinous mass formed of pyroxylin and sensitive salt. After washing for a considerable time, the pellicle was dried naturally or washed with alcohol, and then the pyroxylin redissolved in ether and alcohol, leaving an emulsion of silver bromide, silver chloride or silver iodide, or mixtures of all suspended in collodion. In this state the plate could be coated and dried at once for exposure. Sometimes, in fact generally, preservatives were used, as in the case of dry plates with the bath, in order to prevent the atmosphere from rendering the surface of the film spotty or insensitive on development. This modification had the great advantage of allowing a large quantity of sensitive salt to be prepared of precisely the same value as to rapidity of action and quality of film.

A great advance in the use of the collodion bromide process was made by Colonel Stuart Wortley, who in June 1873 made known the powerful nature of a *strongly* alkaline developer as opposed to the weak one which up to that time had usually been employed for a collodion emulsion plate, or indeed for any dry plate.

An example of the preparation of a collodion emulsion and the developer is the following: 2½ oz. of alcohol, 5 oz. of ether, 75 grains of pyroxylin. In 1 oz. of alcohol are dissolved 200 grains of zinc bromide [2]; it is then acidulated with 4 or 5 drops of nitric acid, and added to half the above collodion. In 2 drachms of water are dissolved 330 grains of silver nitrate, 1 oz. of alcohol being added. The silvered alcohol is next poured into the other half of the collodion and the brominized collodion dropped in, care being taken to shake between the operations. An emulsion of silver bromide is formed in suspension; and it is in every case left for 10 to 20 hours to what is technically called "ripen," or, in other words, to become creamy when poured out upon a glass plate. When the emulsion has ripened it may be used at once or be poured out into a flat dish and the solvents allowed to evaporate till the pyroxylin becomes gelatinous. In this state it is washed in water till all the soluble salts are carried away. After this it may be either spread out on a cloth and dried or treated with two or three doses of alcohol, and then re-dissolved in equal parts of alcohol (specific gravity, ·805) and ether (specific gravity, ·720). In this condition it is a washed emulsion, and a glass plate can be coated with it and the film dried, or it may be washed and some of the many preservatives, such as albumen, beer, coffee, gum, &c., applied.

The type of a useful alkaline developer for collodion plates is as follows:—

1.	Pyrogallic acid	96 grs.
	Alcohol	1 oz.
2.	Potassium bromide	12 grs.
	Water distilled	1 oz.
3.	Ammonium carbonate	80 grs.
	Water	1 oz.

To develop the plate 6 minims of No. 1, ½ drachm of No. 2, and 3 drachms of No. 3 are mixed together and made to flow over the plate after washing the preservative off under the tap. Sometimes the

[1] An account of Sayce's process is to be found in the *Photographic News* of October 1865, or the *Photographic Journal* of the same date.

development is conducted in a flat dish, sometimes the solution is poured on the plate.[1] The unreduced salts are eliminated by either cyanide of potassium or sodium hyposulphite. Intensity may be given to the image, if requisite, either before or after the "fixing" operation. Where resort is had to ferrous oxalate development, the developer is made in one of two ways—(1) by saturating a saturated solution of neutral potassium oxalate with ferrous oxalate, and adding an equal volume of a solution (10 grains to 1 oz. of water) of potassium bromide to restrain the action, or (2) by mixing, according to Eder's plan, 3 volumes by measure of a saturated solution of the potassium oxalate with 1 volume by measure of a saturated solution of ferrous sulphate, and adding to the ferrous oxalate solution thus obtained an equal bulk of the above solution of potassium bromide. The development is conducted in precisely the same manner as indicated above, and the image is fixed by one of the same agents.

Gelatin Emulsion Process.—The facility with which silver bromide emulsion could be prepared in collodion had turned investigation into substitutes for it. As early as September 1871 Dr R. L. Maddox had tried emulsifying the silver salt in gelatin, and had produced negatives of rare excellence. In November 1873 J. King described a similar process, getting rid of the soluble salts by washing. Efforts had also been made in this direction by J. Burgess in July 1873. R. Kennett in 1874 may be said to have been the first to put forward the gelatin emulsion process in a practical and workable form, as he then published a formula which gave good and quick results. It was not till 1878, however, that the great capabilities of silver bromide when held in suspension by gelatin were fairly known; in March of that year C. Bennett showed that by keeping the gelatin solution liquid at a low temperature for as long as seven days extraordinary rapidity was conferred on the sensitive salt. The molecular condition of the silver bromide seemed to be altered, and to be amenable to a far more powerful developer than had hitherto been dreamt of. In 1874 J. S. Stas had shown that various modifications of silver bromide and chloride were possible, and it seemed that the green molecular condition (one of those noted by Stas) of the bromide was attained by prolonged warming. It may be said that the advent of rapid plates was 1878, and that the full credit of this discovery should be allotted to C. Bennett. Both Kennett and Bennett got rid of the soluble salts from the emulsion by washing; and in order to attain success it was requisite that the bromide should be in excess of that necessary to combine with the silver nitrate used to form the emulsion. In June 1879 Abney showed that a good emulsion might be formed by precipitating a silver bromide by dropping a solution of a soluble bromide into a dilute solution of silver nitrate. The supernatant liquid was decanted, and after two or three washings with water the precipitate was mixed with the proper amount of gelatin. D. B. van Monckhoven of Ghent, in experimenting with this process, hit upon the plan of obtaining the emulsion by acting on silver carbonate with hydrobromic acid, which left no soluble salts to be extracted. He further, in August 1879, announced that he had obtained great rapidity by adding to the bromide emulsion a certain quantity of ammonia. This addition rapidly altered the silver bromide from its ordinary state to the green molecular condition referred to above. At this point we have the branching off of the gelatin emulsion process into two great divisions, viz. that in which rapidity was gained by long-continued heating, and the other in which it was gained by the use of ammonia—a subdivision which is maintained to the present day. Opinions as to the merits of the two methods are much divided, some maintaining that the quality of the heated emulsion is better than that produced by alkalinity, and vice versa. We may mention that in 1881 Dr A. Herschel introduced a plan for making an alcoholic gelatin emulsion with the idea of inducing rapid drying of the plates, and in the same year H. W. Vogel of Berlin introduced a method of combining gelatin and pyroxylin together by means of a solvent which acted on the gelatin and allowed the addition of alcohol in order to dissolve the pyroxylin. This "collodio-gelatin emulsion" was only a shortlived process, which is not surprising, since its preparation involved the inhalation of the fumes of acetic acid.

[1] For further details the reader is referred to *Instruction in Photography*, 11th ed., p. 362.

The warming process introduced by Bennett was soon superseded. Colonel Stuart Wortley in 1879 announced that, by raising the temperature of the vessel in which the emulsion was stewed to 150° F., instead of days being required to give the desired sensibility only a few hours were necessary. A further advance was made by boiling the emulsion, first practised, we believe, by G. Mansfield in 1879. Another improvement was effected by W. B. Bolton by emulsifying the silver salt in a small quantity of gelatin and then raising the emulsion to boiling point, boiling it for from half an hour to an hour, when extreme rapidity was attained. Many minor improvements in this process have been made from time to time. It may be useful to give an idea of the relative rapidities of the various processes we have described.

Gelatin Emulsions.

The following is an outline of two representative processes. All operations should be conducted in light which can act but very slightly on the sensitive salts employed, and this is more necessary with this process than with others on account of the extreme ease with which the equilibrium of the molecules is upset in giving rise to the molecule which is developable. The light to work with is gaslight or candle-light passing through a sheet of Chance's stained red glass backed by orange paper. Stained red glass allows but few chemically effective rays to pass through it, whilst the orange paper diffuses the light. If daylight be employed, it is as well to have a double thickness of orange paper. The following should be weighed out:—

1.	Potassium iodide	5 grs.
2.	Potassium bromide.	135 ,,
3.	Nelson's No. 1 photographic gelatin . .	30 ,,
4.	Silver nitrate	175 ,,
5.	Autotype or other hard gelatin . . .	100 ,,
	Nelson's No. 1 gelatin	100 ,,

Nos. 3 and 5 are rapidly covered with water or washed for a few seconds under the tap to get rid of any dust. No. 2 is dissolved in 1½ oz. of water, and a little tincture of iodine added till it assumes a light sherry colour. No. 1 is dissolved in 60 minims of water. No. 4 is dissolved in ½ oz. of water, and No. 3 is allowed to swell up in 1 oz. of water, and is then dissolved by heat. All the flasks containing these solutions are placed in water at 150° F. and carried into the "dark room," as the orange-lighted chamber is ordinarily called; Nos. 3 and 4 are then mixed together in a jar or flask, and No. 2 added drop by drop till half its bulk is gone, when No. 1 is added to the remainder, and the double solution is dropped in as before. When all is added there ought to be formed an emulsion which is very ruddy when examined by gaslight, or orange by daylight. The flask containing the emulsion is next placed in boiling water, which is kept in a state of ebullition for about three-quarters of an hour. It is then ready, when the contents of the flask have cooled down to about 100° F., for the addition of No. 5, which should in the interval be placed in 2 oz. of water to swell and finally be dissolved. The gelatin emulsion thus formed is placed in a cool place to set, after which it is turned into a piece of coarse canvas or mosquito netting made into a bag. By squeezing, threads of gelatin containing the sensitive salt can be made to fall into cold water; by this means the soluble salts are extracted. This is readily done in two or three hours by frequently changing the water, or by allowing running water to flow over the emulsion-threads. The gelatin is next drained by straining canvas over a jar and turning out the threads on to it, after which it is placed in a flask, and warmed till it dissolves, half an ounce of alcohol being added. Finally it is filtered through chamois leather or swansdown calico. In this state it is ready for the plates.

The other method of forming the emulsion is with ammonia. The same quantities as before are weighed out, but the solutions of Nos. 2 and 3 are first mixed together and No. 4 is dissolved in 1 oz. of water, and strong ammonia of specific gravity ·880 added to it till the oxide first precipitated is just redissolved. This solution is then dropped into Nos. 2 and 3 as previously described, and finally No. 1 is added. In this case no boiling is required; but to secure rapidity it is as well that the emulsion should be kept an hour at a temperature of about 90° F., after which half the total quantity of No. 5 is added. When set the emulsion is washed, drained, and redissolved as before; but in order to give tenacity

to the gelatin the remainder of No. 5 is added *before* the addition of the alcohol, and *before* filtering.

Coating the Plates.—Glass plates are best cleaned with nitric acid, rinsed, and then treated with potash solution, rinsed again, and dried with a clean cloth. They are then ready for receiving the emulsion, which, after being warmed to about 120° F., is poured on them to cover well the surface. This being done, the plates are placed on a level shelf and allowed to stay there till the gelatin is thoroughly set; they are then put in a drying cupboard, through which a current of warm air is made to pass. It should be remarked that the warmth is only necessary to enable the air to take up the moisture from the plates. They ought to dry in about twelve hours, and they are ready for use.

Exposure.—With a good emulsion and on a bright day the exposure of a plate to a landscape, with a lens whose aperture is one-sixteenth that of the focal distance, should not be more than one-half to one-fifth of a second. This time depends, of course, on the nature of the view; if there be foliage in the immediate foreground it will be longer. In the portrait-studio, under the same circumstances, an exposure with a portrait lens may be from half a second to four or five seconds.

Development of the Plate.—To develop the image either a ferrous oxalate solution or alkaline pyrogallic acid may be used. No chemical restrainer such as potassium bromide is necessary, since the gelatin itself acts as a physical restrainer. If the alkaline developer be used, the following may be taken as a good standard:—

1.	Pyrogallol	50 grs.
	Citric acid	10 „
	Water	1 oz.
2.	Potassium bromide	10 grs.
	Water	1 oz.
3.	Ammonia, ·880	1 dr.
	Water	9 „

One dram of each of these is taken and the mixture made up to 2 oz. with water. The plate is placed in a dish and the above poured over it without stoppage, whereupon the image gradually appears and, if the exposure has been properly timed, gains sufficient density for printing purposes. It is fixed in a solution of hyposulphite of soda, as in the other processes already described, and then thoroughly washed for two or three hours to eliminate all the soluble salt. This long washing is necessary on account of the nature of the gelatin.

Intensifying the Negative.—Sometimes it is necessary to intensify the negative, which can be done in a variety of ways with mercury salts. An excellent plan, introduced by Chapman Jones, is to use a saturated solution of mercuric chloride in water. After thorough washing the negative is treated with ferrous oxalate. This process can be repeated till sufficient density is attained. With most other methods with mercury the image is apt to become yellow and to fade; with this apparently it is not.

Varnishing the Negative.—The negative is often protected by receiving first a film of plain collodion and then a coat of shellac or other photographic varnish. This protects the gelatin from moisture and also from becoming stained with the silver nitrate owing to contact with the sensitive paper used in silver printing. Another varnish is a solution of celloidin in amyl acetate. This is an excellent protection against damp.

Printing Processes.

The first printing process may be said to be that of Fox Talbot (see above), which has continued to be generally employed (with the addition of albumen to give a surface to the print—an addition first made, we believe, by Fox Talbot).

Paper for printing is prepared by mixing 150 parts of ammonium chloride with 240 parts of spirits of wine and 2000 parts of water, though the proportions may vary. These ingredients are dissolved, and the whites of fifteen fairly-sized eggs are added and the whole beaten up to a froth. In hot weather it is advisable to add a drop of carbolic acid to prevent decomposition. The albumen is allowed two or three days to settle, when it is filtered through a sponge placed in a funnel, or through two or three thicknesses of fine muslin, and transferred to a flat dish. The paper is cut of convenient size and allowed to float on the solution for about a minute, when it is taken off and dried in a warm room. For dead prints, on which colouring is to take place, plain salted paper is useful. It can be made of the following proportions—90 parts of ammonium chloride, 100 parts of sodium citrate, 10 parts of gelatin, 5000 parts of distilled water. The gelatin is first dissolved in hot water and the remaining components are added. It is next filtered, and the paper allowed to float on it for three minutes, then withdrawn and dried.

Sensitizing Bath.—To sensitize the paper it is floated on a 10 % solution of silver nitrate for three minutes. It is then hung up and allowed to dry, after which it is ready for use. To print the image the paper is placed in a printing frame over a negative and exposed to light. It is allowed to print till such time as the image appears rather darker than it should finally appear.

Toning and Fixing the Print.—The next operation is to tone and fix the print. In the earlier days this was accomplished by means of a bath of *sel d'or*—a mixture of hyposulphite of soda and gold chloride. This gilded the darkened parts of the print which light had reduced to the semi-metallic state: and on the removal of the chloride by means of hyposulphite an image composed of metallic silver, an organic salt of silver and gold was left behind. There was a suspicion, however, that part of the coloration was due to a combination of sulphur with the silver, not that pure silver sulphide is in any degree fugitive, but the sulphuretted organic salt of silver seems to be liable to change. This gave place to a method of alkaline toning, or rather, we should say, of neutral toning, by employing gold chloride with a salt, such as the carbonate or acetate of soda, chloride of lime, borax, &c. By this means there was no danger of sulphurization during the toning, to which the method by *sel d'or* was prone owing to the decomposition of the hyposulphite. The substances which can be employed in toning seem to be those in which an alkaline base is combined with a weak acid, the latter being readily displaced by a stronger acid, such as nitric acid, which must exist in the paper after printing. This branch of photography owes much to the Rev. T. F. Hardwich, he having carried on extensive researches in connexion with it during 1854 and subsequent years. A. Davanne and A. Girard, a little later, also investigated the matter with fruitful results.

The following may be taken as two typical toning-baths:—

	Gold chloride	1 part.
	Sodium carbonate	10 parts.
	Water	5000 „
(α)	Borax	100 „
	Water	4000 „
(β)	Gold chloride	1 part.
	Water	4000 parts

In the latter (α) and (β) are mixed in equal parts immediately before use. Each of these is better used only once. A third bath is:—

Gold chloride	2 parts.
Chloride of lime	2 „
Chalk	40 „
Water	8000 „

These are mixed together, the water being warmed. When cool the solution is ready for use. In toning prints there is a distinct difference in the *modus operandi* according to the toning-bath employed. Thus in the first two baths the print must be thoroughly washed in water to remove all free silver nitrate, that salt forming no part in the chemical reactions. On the other hand, where free chlorine is used, the presence of free silver nitrate or some active chlorine absorbent is a necessity. In 1872 Abney showed that with such a toning-bath free silver nitrate might be eliminated, and if the print were immersed in a solution of a salt such as lead nitrate the toning action proceeded rapidly and without causing any fading of the image whilst toning, which was not the case when the free silver nitrate was totally removed and no other chlorine absorbent substituted. This was an important factor, and one which had been overlooked. In the third bath the free silver nitrate should only be partially removed by washing. The print, having been partially washed or thoroughly washed, as the case may be, is immersed in the toning-bath till the image attains a purple or bluish tone, after which it is ready for fixing. The solution used for this purpose is a 20 % solution of hyposulphite of soda, to which it is best to add a few drops of ammonia in order to render it alkaline. About ten minutes suffice to effect the conversion of the chloride into hyposulphite of silver, which is soluble in hyposulphite of soda and can be removed by washing. The organic salts of silver seem, however, to form a different salt, which is partially insoluble, but which the ammonia helps to remove. If it is not removed there is a sulphur compound left behind, according to J. Spiller, which by time and exposure becomes yellow.

The use of potassium cyanide for fixing prints is to be avoided, as this reagent attacks the organic coloured oxide which, if removed, would render the print a ghost. The washing of silver prints should be very complete, since it is said that the least trace of hyposulphite left behind renders the fading of the image a mere matter of time. The stability of a print has been supposed to be increased by immersing it, after washing, in a solution of alum. The alum, like any acid body, decomposes the hyposulphite into suphur and sulphurous acid. If this be the case, it seems probable that the destruction of the hyposulphite by time is not the occasion of fading, but that its hygroscopic character is. This, however, is a moot point. It is usual to wash the prints some hours in running water. We have found that half a dozen changes of water, and between successive changes the application of a sponge to the back of each print separately, are equally or more efficacious. On drying the print assumes a darker tone than it has after leaving the fixing bath.

Different tones can thus be given to a print by different toning-baths; and the gold itself may be deposited in a ruddy form or in a blue form. The former molecular condition gives the red and sepia tones, and the latter the blue and black tones. The degree of minute subdivision of the gold may be conceived when it is

stated that, on a couple of sheets of albuminized paper fully printed, the gold necessary to give a decided tone does not exceed half a grain.

Collodio-chloride Silver Printing Process.—In the history of the emulsion processes we stated that Gaudin attempted to use silver chloride suspended in collodion, but it was not till the year 1864 that any practical use was made of the suggestion so far as silver printing is concerned. In the autumn of that year George Wharton Simpson worked out a method which has been more or less successfully employed. The formula appended is Simpson's:—

1.	Silver nitrate	60 parts.
	Distilled water	60 "
2.	Strontium chloride	64 "
	Alcohol	1000 "
3.	Citric acid	64 "
	Alcohol	1000 "

To every 1000 parts of plain collodion 30 parts of No. 1, previously mixed with 60 parts of alcohol, are added; 60 parts of No. 2 are next mixed with the collodion, and finally 30 parts of No. 3. This forms an emulsion of silver chloride and also contains citric acid and silver nitrate. The defect of this emulsion is that it contains a large proportion of soluble salts, which are apt to crystallize out on drying, more particularly if it be applied to glass plates. The addition of the citric acid and the excess of silver nitrate is the key to the whole process; for, unless some body were present which on exposure to light was capable of forming a highly coloured organic oxide of silver, no vigour would be obtained in printing. If pure chloride be used, though an apparently strong image would be obtained, yet on fixing only a feeble trace of it would be left, and the print would be worthless. The collodio-chloride emulsion may be applied to glass, or to paper, and the printing carried on in the usual manner. The toning takes place by means of the chloride of lime or by ammonium sulphocyanide and gold, which is practically a return to the *sel d'or* bath. The organic salt formed in this procedure does not seem so prone to be decomposed by keeping as does that formed by albumen, and the washing can be more completely carried out. There are in the market several papers which are collodio-chloride.

Gelatino-citro-chloride Emulsion.—A modified emulsion printing process was introduced by Abney in 1881, which consisted in suspending silver chloride and silver citrate in gelatin, there being no excess of silver present. The formula of producing it is as follows:—

1.	Sodium chloride	40 parts.
	Potassium citrate	40 "
	Water	500 "
2.	Silver nitrate	150 "
	Water	500 "
3.	Gelatin	300 "
	Water	1700 "

Nos. 2 and 3 are mixed together whilst warm, and No. 1 is then gently added, the gelatin solution being kept in brisk agitation. This produces the emulsion of citrate and chloride of silver. The gelatin containing the suspended salts is heated for five minutes at boiling point, when it is allowed to cool and subsequently slightly washed, as in the gelatino-bromide emulsion. It is then ready for application to paper or glass. The prints are of a beautiful colour, and seem to be fairly permanent. They may be readily toned by the borax or by the chloride of lime toning-bath, and are fixed with the hyposulphite solution of the strength before given. Most, if not all, of the gelatin papers now extant are made somewhat after this manner.

Printing with Salts of Uranium.—The sensitiveness of the salts of uranium to light seems to have been discovered by Niepce, and was subsequently applied to photography by J. E. Burnett in England. One of the original formulae consisted of 20 parts of uranic nitrate with 600 parts of water. Paper, which is better if slightly sized previously with gelatin, is floated on this solution. When dry it is exposed beneath a negative, and a very faint image is produced; but it can be developed into a strong one by 6 to 10 % solution of silver nitrate to which a trace of acetic acid has been added, or by a 2 % solution of gold chloride. In both these cases the silver and gold are deposited in the metallic state. Another developer is a 2 % solution of potassium ferrocyanide to which a trace of nitric acid has been added, sufficient to give a red coloration. The development takes place most readily by letting the paper float on these solutions.

Self-toning Papers.—There are several self-toning papers based on the chloride emulsion process. These contain the necessary amount of gold to tone the print. The print is produced in the ordinary way and then immersed in salt and water or in some cases potassium sulphocyanide. The print is finished by immersing in weak hyposulphite of soda.

Printing with Chromates: Carbon Prints.—The first mention of the use of potassium bichromate for printing purposes seems to have been made by Mungo Ponton in May 1839, when he stated that paper, if saturated with this salt and dried, and then exposed to the sun's rays through a drawing, would produce a yellow picture on an orange ground, nothing more being required to fix it than washing it in water, when a white picture on an orange ground was obtained. In 1840 Edmond Becquerel announced that paper sized with iodide of starch and soaked in potassium bichromate was, on drying, more sensitive than unsized paper. Joseph Dixon of Massachusetts, in the following year, produced copies of bank-notes by using gum arabic with potassium bichromate spread upon a lithographic stone, and, after exposure of the sensitive surface through a bank-note, by washing away the unaltered gum and inking the stone as in ordinary lithography. The same process, with slight modifications, has been used by Simonau and Toovey of Brussels, and produces excellent results. Dixon's method, however, was published in the *Scientific American* for 1854, and consequently, as regards priority, it ranks after Fox Talbot's photo-engraving process (see below), published in 1852. On the 13th of December 1855 Alphonse Poitevin took out a patent in England, in which he vaguely described a method of taking a direct carbon-print by rendering gelatin insoluble through the action of light on potassium bichromate. This idea was taken up by John Pouncey of Dorchester, who perhaps was the first to produce veritable carbon-prints, notwithstanding that Testud de Beauregard took out a somewhat similar patent to Poitevin's at the end of 1857.

Pouncey published his process on the 1st of January 1859; but, as described by him, it was by no means in a perfect state, half-tones being wanting. The cause of this was first pointed out by Abbé Laborde in 1858, whilst describing a kindred process in a note to the French Photographic Society. He says, "In the sensitive film, however thin it may be, two distinct surfaces must be recognized—an outer, and an inner which is in contact with the paper. The action of light commences on the outer surface; in the washing, therefore, the half-tones lose their hold on the paper and are washed away." J. C. Burnett in 1858 was the first to endeavour to get rid of this defect in carbon printing. In a paper to the Photographic Society of London he says, "There are two essential requisites . . . (2) that in printing the paper should have its *un*prepared side (and not its prepared side, as in ordinary printing) placed in contact with the negative in the pressure-frame, as it is only by printing in this way that we can expect to be able afterwards to remove by washing the unacted-upon portions of the mixture. In a positive of this sort printed from the front or prepared side the attainment of half-tones by washing away more or less depth of the mixture, according to the depth to which it has been hardened, is prevented by the insoluble parts being on the surface and in consequence protecting the soluble part from the action of the water used in washing; so that either nothing is removed, or by steeping very long till the inner soluble part is sufficiently softened the whole depth comes bodily away, leaving the paper white." This method of exposing through the back of the paper was crude and unsatisfactory, and in 1860 Fargier patented a process in which, after exposure to light of the gelatin film which contained pigment, the surface was coated with collodion, and the print placed in warm water, where it separated from the paper support and could be transferred to glass. Poitevin successfully opposed this patent, for he had used this means of detaching the films in his powder-carbon process, in which ferric chloride and tartaric acid were used. Fargier at any rate gave an impetus to carbon-printing, and J. W. Swan took up the matter, and in 1864 secured a patent. One of the great features in Swan's innovations was the production of what is now known as "carbon-tissue," made by coating paper with a mixture of gelatin, sugar and colouring matter, and rendered sensitive to light by means of potassium or ammonium bichromate. After exposure to light Swan placed the printed carbon-tissue on an india-rubber surface, to which it was made to adhere by pressure. The print was immersed in hot water, the paper backing stripped off, and the soluble gelatin containing colouring matter washed away. The picture could then be retransferred to its final support of paper. In 1869 J. R. Johnson of London took out a patent in which he claimed that carbon-tissue which had been soaked in water for a short period, by its tendency to swell further, would adhere to any waterproof surface such as glass, metal, waxed paper, &c., without any adhesive material being applied. This was a most important improvement. Johnson also applied soap to the gelatin to prevent its excessive brittleness on drying, and made its final support of gelatinized paper, rendered insoluble by chrome alum. In 1874 J. R. Sawyer patented a flexible support for developing on; this was a sized paper coated with gelatin and treated with an ammoniacal solution of shellac in borax, on which wax or resin was rubbed. The advantage of this flexible support is that the dark parts of the picture have no tendency to contract from the lighter parts, which they were apt to do when a metal plate was used, as was the case in Johnson's original process. With this patent, and minor improvements made since, carbon-printing has arrived at its present state of perfection.

According to P. E. Liesegang, the carbon-tissue when prepared on a large scale consists of from 120 to 150 grains of gelatin (a soft kind), 15 grains of soap, 21 grains of sugar and from 4 to 8 grains of dry colouring matter. The last-named may be of various kinds, from lamp-black pigment to soluble colours such as alizarin. The gelatin, sugar and soap are put in water and allowed to stand for an hour, and then melted, the liquid afterwards receiving the

colours, which have been ground on a slab. The mixture is filtered through fine muslin. In making the tissue in large quantities the two ends of a piece of roll-paper are pasted together and the paper hung on two rollers; one of wood about 5 in. in diameter is fixed near the top of the room and the other over a trough containing the gelatin solution, the paper being brought into contact with the surface of the gelatin by being made to revolve on the rollers. The thickness of the coating is proportional to the rate at which the paper is drawn over the gelatin: the slower the movement, the thicker the coating. The paper is taken off the rollers, cut through, and hung up to dry on wooden laths. If it be required to make the tissue sensitive at once, 120 grains of potassium bichromate should be mixed with the ingredients in the above formula. The carbon-tissue when prepared should be floated on a sensitizing bath consisting of one part of potassium bichromate in 40 parts of water. This is effected by turning up about 1 in. from the end of the sheet of tissue (cut to the proper size), making a roll of it, and letting it unroll along the surface of the sensitizing solution, where it is allowed to remain till the gelatin film feels soft. It is then taken off and hung up to dry in a dark room through which a current of dry warm air is passing. Tissue dried quickly, though not so sensitive, is more manageable to work than if more slowly dried. As the issue is coloured, it is not possible to ascertain by inspection whether the printing operation is sufficiently carried out, and in order to ascertain this it is usual to place a piece of ordinary silvered paper in an actinometer, or photometer, alongside the carbon-tissue to ascertain the amount of light that has acted on it. There are several devices for ascertaining this amount, the simplest being an arrangement of a varying number of thicknesses of gold-beater's skin. The value of 1, 2, 3, &c., thicknesses of the skin as a screen to the light is ascertained by experiment. Supposing it is judged that a sheet of tissue under some one negative ought to be exposed to light corresponding to a given number of thicknesses, chloride of silver paper is placed alongside the negative beneath the actinometer and allowed to remain there until it takes a visible tint beneath a number of thicknesses equivalent to the strength of the negative. After the tissue is removed from the printing-frame—supposing a double transfer is to be made—it is placed in a dish of cold water, face downwards, along with a piece of Sawyer's flexible support. When the edges of the tissue begin to curl up, its surface and that of the flexible support are brought together and placed flat. The water is pressed out with an india-rubber squeezer or "squeegee" and the two surfaces adhere. About a couple of minutes later they are placed in warm water of about 90° to 100° F., and the paper of the tissue, loosened by the gelatin solution next it becoming soluble, can be stripped off, leaving the image (reversed as regards right and left) on the flexible support. An application of warm water removes the rest of the soluble gelatin and pigment. When dried the image is transferred to its permanent support. This usually consists of white paper coated with gelatin and made insoluble with chrome alum, though it may be mixed with barium sulphate or other similar pigments. This transfer-paper is made to receive the image by being soaked in hot water till it becomes slimy to the touch; and the surface of the damped print is brought into contact with the surface of the re-transfer-paper in the same manner as was done with the flexible support and the carbon-tissue. When dry the retransfer-paper bearing the gelatin image can be stripped off the flexible support, which may be used again as a temporary support for other pictures. If a *reversed* negative be used the image may be transferred at once to its *final* support instead of to the temporary flexible support, which is a point of practical value, since single-transfer are better than double-transfer prints.

Printing with Salts of Iron.—Sir John Herschel and Robert Hunt entered into various methods of printing with salts of iron. At the present time two or three are practised, being used in draughtsmen's offices for copying tracings (see SUN-COPYING).

Photo-mechanical Printing Processes.—Poitevin claimed to have discovered that a film of gelatin impregnated with potassium bichromate, after being acted upon by light and damping, would receive greasy ink on those parts which had been affected by light. But Paul Oreloth seems to have made the discovery previous to 1854, for in his patent of that year he states that his designs were inked with printing ink before being transferred to stone or zinc. C. M. Tessie de Motay (in 1865) and C. R. Marechal of Metz, however, seem to have been the first to produce half-tones from gelatin films by means of greasy ink. Their general procedure consisted in coating metallic plates with gelatin impregnated with potassium or ammonium bichromate or tri-chromate and mercuric chloride, then treating with silver oleate, exposing to light through a negative, washing, inking with a lithographic roller, and printing from the plates as for an ordinary lithograph. The half-tints by this process were very good, and illustrations executed by it are to be found in several existing works. The method of producing the plates, however, was most laborious, and it was simplified by A. Albert of Munich. He had been experimenting for many years, endeavouring to make the gelatin films more durable than those of Tessie de Motay. He added gum-resins, alum, tannin and other such matters, which had the property of hardening gelatin; but the difficulty of adding sufficient to the mass in its liquid state before the whole became coagulated rendered these unmanageable. It at last occurred to him that if the hardening action of light were utilized by exposing the surface next the plate to light after or before exposing the front surface to the film and the image, the necessary hardness might be given to the gelatin without adding any chemical hardeners to it. In Tessie de Motay's process the hardening was almost absent, and the plates were consequently not durable. It is evident that to effect this one of two things had to be done: either the metallic plate used by Tessie de Motay must be abandoned, or else the film must be stripped off the plate and exposed in that manner. Albert adopted the transparent plate, and his success was assured, since instead of less than a hundred impressions being pulled from one plate he was able to take over a thousand. This occurred about 1867, but the formula was not published for two or three years afterwards, when it was divulged by Ohm and Grossman, one of whom had been employed by Albert of Munich, and had endeavoured to introduce a process which resembled Albert's earlier efforts. The name of "Lichtdruck" was given about this time to these surface-printing processes, and Albert may be considered, if not the inventor, at all events the perfecter of the method. Another modification of "Lichtdruck" was patented in England by Ernest Edwards under the name of "heliotype."

Woodbury Type.—This process was invented by W. Woodbury about the year 1864, though we believe that J. W. Swan had been working independently in the same direction about the same time. In October 1864 a description of the invention was given in the *Photographic News*. Marc Antoine A. Gaudin claimed the principle of the process, insisting that it was old, and basing his pretensions on the fact that he had printed with translucent ink from intaglio blocks engraved by hand; but at the same time he remarked that the application of the principle might lead to important results. It was just these results which Woodbury obtained, and for which he was entitled to the fullest credit. Woodbury subsequently introduced certain modifications, the outcome being what is known as the "stannotype process," of which in 1880 he read a description before the French Photographic Society (see PROCESS).

Photo-lithography.—Reference has been made to the effect of light on gelatin impregnated with potassium bichromate, whereby the gelatin becomes insoluble, and also incapable of absorbing water where the action of the light has had full play. It is this last phenomenon which occupies such an important place in photo-lithography. In the spring of 1859 E. J. Asser of Amsterdam produced photographs on a paper basis in printer's ink. Being anxious to produce copies of such prints mechanically, he conceived the idea of transferring the greasy ink impression to stone, and multiplying the impressions by mechanical lithography. Following very closely upon Asser, J. W. Osborne of Melbourne made a similar application; his process is described by himself in the *Photographic Journal* for April 1860 as follows: "A negative is produced in the usual way, bearing to the original the desired ratio. . . . A positive is printed from this negative upon a sheet of (gelatinized) paper, so prepared that the image can be transferred to stone, it having been previously covered with greasy printer's ink. The impression is developed by washing away the soluble matter with hot water, which leaves the ink on the lines of print of the map or engraving." The process of transferring is accomplished in the ordinary way. Early in 1860 Colonel Sir H. James, R.E., F.R.S., brought forward the Southampton method of photo-lithography, which had been carefully worked out by Captain de Courcy Scott, R.E. The "papyrotype process" was published by Abney in 1870 (see LITHOGRAPHY and PROCESS).

Photographs in Natural Colours.

The first notice on record of coloured light impressing its own colours on a sensitive surface is in the passage already quoted from the *Farbenlehre* of Goethe, where T. J. Seebeck of Jena (1810) describes the impression he obtained on paper impregnated with moist silver chloride. In 1839 Sir J. Herschel (*Athenaeum*, No. 621) gave a somewhat similar description. In 1848 Edmond Becquerel succeeded in reproducing upon a daguerreotype plate not only the colours of the spectrum but also, up to a certain point, the colours of drawings and objects. His method of proceeding was to give the silver plate a thin coating of silver chloride by immersing it in ferric or cupric chlorides. It may also be immersed in chlorine water till it takes a feeble rose tint. Becquerel preferred to chlorinize the plate by immersion in a solution of hydrochloric acid in water, attaching it to the positive pole of a voltaic couple, whilst the other pole he attached to a platinum plate also immersed in the acid solution. After a minute's subjection to the current the plate took successively a grey, a yellow, a violet and a blue tint, which order was again repeated. When the violet tint appeared for the second time the plate was withdrawn and washed and dried over a spirit-lamp. In this state it

produced the spectrum colours, but it was found better to heat the plate till it assumed a rose tint. At a later date Niepce de St Victor chlorinized by chloride of lime, and made the surface more sensitive by applying a solution of lead chloride in dextrin. G. W. Simpson also obtained coloured images on silver chloride emulsion in collodion, but they were less vivid and satisfactory than those obtained on daguerreotype plates. Poitevin obtained coloured images on ordinary silver chloride paper by preparing it in the usual manner and washing it and exposing it to light. It was afterwards treated with a solution of potassium bichromate and cupric sulphate, and dried in darkness. Sheets so prepared gave coloured images from coloured pictures, which he stated could be fixed by sulphuric acid (*Comptes rendus*, 1868, 61, p. 11). In the *Bulletin de la Société Française* (1874) Colonel St Florent described experiments which he made with the same object. He immersed ordinary or albuminized paper in silver nitrate and afterwards plunged it into a solution of uranium nitrate and zinc chloride acidulated with hydrochloric acid; it was then exposed to light till it took a violet, blue or lavender tint. Before exposure the paper was floated on a solution of mercuric nitrate, its surface dried, and exposed to a coloured image.

It is supposed—though it is very doubtful if it be so—that the nature of the chloride used to obtain the silver chloride has a great effect on the colours impressed; and Niepce in 1857 made some observations on the relationship which seemed to exist between the coloured flames produced by the metal and the colour impressed on a plate prepared with a chloride of such a metal. In 1880 Abney showed that the production of colour really resulted from the oxidation of the chloride that was coloured by light. Plates immersed in a solution of hydrogen peroxide took the colours of the spectrum much more rapidly than when not immersed, and the size of the molecules seemed to regulate the colour. He further stated that the whole of the spectrum colours might be derived from a mixture of two or at most three sizes of molecules.

In 1841 Robert Hunt published some results of colour-photography by means of silver fluoride. A paper was washed with silver nitrate and with sodium fluoride, and afterwards exposed to the spectrum. The action of the spectrum commenced at the centre of the yellow ray and rapidly proceeded upwards, arriving at its maximum in the blue ray. As far as the indigo the action was uniform, whilst in the violet the paper took a brown tint. When it was previously exposed, however, a yellow space was occupied where the yellow rays had acted, a green band where the green had acted, whilst in the blue and indigo it took an intense blue, and over the violet there was a ruddy brown. In reference to these coloured images on paper it must not be forgotten that pure salts of silver are not being dealt with as a rule. An organic salt of silver is usually mixed with silver chloride paper, the organic salt being due to the sizing of the paper, which towards the red end of the spectrum is usually more sensitive than the chloride. If a piece of ordinary silver chloride paper is exposed to the spectrum till an impression is made, it will usually be found that the blue colour of the darkened chloride is mixed with that due to the coloration of the darkened organic compound of silver in the violet region, whereas in the blue and green this organic compound is alone affected, and is of a different colour from that of the darkened mixed chloride and organic compound. This naturally gives an impression that the different rays yield different tints, whereas this result is simply owing to the different range of sensitiveness of the bodies. In the case of the silver chlorinized plate and of true collodio-chloride, in which no organic salt has been dissolved, we have a true coloration by the spectrum. At present there is no means of permanently fixing the coloured images which have been obtained, the effect of light being to destroy them. If protected from oxygen they last longer than if they have free access to it, as is the case when the surface is exposed to the air.

A method devised by Gabrielle Lippmann, of Paris, by which the natural colours of objects are reproduced by means of interference, may be briefly described as follows: A sensitive plate is placed in contact with a film of mercury, and the exposure to the spectrum, or to the image of coloured objects to be photographed, is made through the back of the plate. On development, the image appears coloured when viewed at one particular angle, the colours being approximately those of the object. The necessary exposure to produce this result was very prolonged in the first experiments in which the spectrum was photographed, and a longer exposure had to be given to the red than was required for the blue. Lippmann at first employed collodion dry plates, prepared, it is believed, with albumen, and it required considerable manipulation to bring out the colours correctly. A. Lumière used gelatin plates dyed with appropriate dyes (orthochromatic plates); the exposure was much diminished, and very excellent representations were produced of all natural colours. The main point to aim at in the preparation of the plate seems to be to obtain a very sensitive film without any, or, at all events, with the least possible, "grain" in the sensitive salt. A formula published by Lumière seems to attain this object. Viewed directly, the developed images appear like ordinary negatives, but when held at an angle to the light the colours are vivid. They are not pure monochromatic colours, but have very much the quality of colours obtained by polarized light. It appears that they are produced by what may be termed "nodes" of different-coloured lights acting within the film. Thus in photographing the spectrum, rays penetrate to the reflecting mercury and are reflected back from it, and these, with the incident waves of light, form nodes where no motion exists, in a somewhat similar way to those obtained in a cord stretched between two points when plucked. In the negative these nodal points are found in the thickness of the silver deposit. When white light is sent through the film after the image has been developed, theoretically only rays of the wave-lengths which formed these nodes are reflected to the eye, and thus we get an impression of colour.

Action of Light on Chemical Compounds.

Reference has been made above to early investigations on the chemical action of light. In 1777 Karl Wilhelm Scheele (Hunt's *Researches in Light*) made the following experiments on silver salts:—

"I precipitated a solution of silver by sal-ammoniac; then I edulcorated it and dried the precipitate and exposed it to the beams of the sun for two weeks; after which I stirred the powder, and repeated the same several times. Hereupon I poured some caustic spirit of sal ammoniac (strong ammonia) on this, in all appearance, black powder, and set it by for digestion. This menstruum dissolved a quantity of *luna cornua* (horn silver), though some black powder remained undissolved. The powder having been washed was, for the greater part, dissolved by a pure acid of nitre (nitric acid), which, by the operation, acquired volatility. This solution I precipitated again by means of sal-ammoniac into horn silver. Hence it follows that the blackness which the luna cornua acquires from the sun's light, and likewise the solution of silver poured on chalk, is *silver by reduction*. . . . I mixed so much of distilled water with well-edulcorated horn silver as would just cover this powder. The half of this mixture I poured into a white crystal phial, exposed it to the beams of the sun, and shook it several times each day; the other half I set in a dark place. After having exposed the one mixture during the space of two weeks, I filtrated the water standing over the horn silver, grown already black; I let some of this water fall by drops in a solution of silver, which was immediately precipitated into horn silver."

This, as far as we know, is the first intimation of the reducing action of light. From this it is evident that Scheele had found that the silver chloride was decomposed by the action of light liberating some form of chlorine. Others have repeated these experiments and found that chlorine is really liberated from the chloride; but it is necessary that some body should be present which would absorb the chlorine, or, at all events, that the chlorine should be free to escape. A tube of dried silver chloride, sealed up *in vacuo*, will not discolour in the light, but keeps its ordinary white colour. A pretty experiment is to seal up *in vacuo*, at one end of a bent tube, perfectly dry chloride, and at the other a drop of mercury. The mercury vapour volatilizes to a certain extent and fills the tube. When exposed to light chlorine is liberated from the chloride, and calomel forms on the sides of the tube. In this case the chloride darkens. Again, dried chloride sealed up in dry hydrogen discolours, owing to the combination of the chlorine with the hydrogen. Poitevin and H. W. Vogel first enunciated the law that for the reduction by light of the haloid salts of silver halogen absorbents were necessary, and it was by following out this law that the present rapidity in obtaining camera images has been rendered possible. To put it briefly, then, the *visible* action of light is a reducing action, which is aided by or entirely due to the fact that other bodies are present which will absorb the halogens.

In the above we have alluded to the *visible* results on silver salts. It by no means follows that the exposure of a silver salt to light for such a brief period as to leave no visible effect must be due to the same effect, that is, that any of the molecules are absolutely reduced or split up by the light. That this or some other action takes place is shown by the fact that the silver salt is capable of alkaline development, that is, the particles

which have suffered a change in their molecules can be reduced to metallic silver, whilst those which have not been acted upon remain unaltered by the same chemical agency. Two theories have been offered to explain the invisible change which takes place in the salts of silver. One is based on the supposition that the molecules of the salt can rearrange their atoms under the vibrations caused by the ether waves placing them in more unstable positions than they were in before the impact of light took place. This, it is presumed, would allow the developer to separate the atoms of such shaken molecules when it came in contact with them. The other theory is that, as in the case of the visible effects of light, some of the molecules are at once reduced and that the developer finishes the disintegration which the light has begun. In the case of the alkaline development the unaltered molecules next those primarily reduced combine with the reduced silver atom and again form an unstable compound and are in their turn reduced.

The first theory would require some such action as that just mentioned to take place and cause the invisible image formed by the shaking apart of the light-stricken molecules to become visible. It is hard to see why other unacted upon molecules close to those which were made unstable and which have been shaken apart by the developer should themselves be placed in unstable equilibrium and amenable to reduction. In the second theory, called the "chemical theory," the reduction is perfectly easy to understand. Abney adopts the chemical theory as the balance of unsubstantiated evidence is in its favour. There is another action which seems to occur almost simultaneously when exposure takes place in the absence of an active halogen absorbent, as is the case when the exposure is given in the air, that is, an oxidizing action occurs. The molecules of the altered haloid salts take up oxygen and form oxides. If a sensitive salt be briefly exposed to light and then treated with an oxidizing substance, such as potassium bichromate, potassium permanganate, hydrogen peroxide, ozone, an image is not developed, but remains unaltered, showing that a change has been effected in the compound which under ordinary circumstances is developable. If such an oxidized salt be treated very cautiously with nascent hydrogen, the oxygen is withdrawn and the image is again capable of development.[1]

Spectrum Effects on Silver Compounds.—The next inquiry is as to the effect of the spectrum on the different silver compounds. We have already described Seebeck's (1810) experiments on silver chloride with the spectrum whereby he obtained coloured photographs, but Scheele in 1777 allowed a spectrum to fall on the same material, and found that it blackened much more readily in the violet rays than in any other. Senebier's experiments have been already quoted. We merely mention these

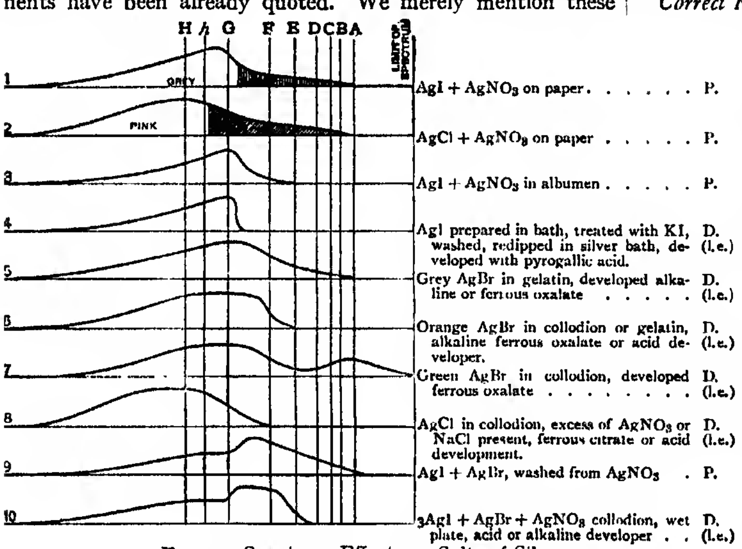

FIG. 1.—Spectrum Effects on Salts of Silver.
[P. = print; D. = developed; l.e. = long exposure.]

two for their historical interest, and pass on to the study of the action of the spectrum on different compounds by Sir J. Herschel (*Phil. Trans.*, 1840). He describes many experiments, which have become the foundation of nearly all subsequent researches of the same kind. The effects of the spectrum have been studied by various experimenters since that time, amongst whom we may mention Edmond Becquerel, John William Draper Alphonse Louis Poitevin, H. W. Vogel, Victor Schumann and W. de W. Abney. Fig. 1 is compiled from a cut which appeared in the *Proc. Roy. Soc.* for 1882, and shows the researches made by Abney as regards the action of the spectrum on the three principal haloid salts of silver. No. 7 shows the effect of the spectrum on a peculiar modification of silver bromide made by Abney, which is seen to be sensitive to the infra-red rays.

Effect of Dyes on Sensitive Films.—In 1874 Dr H. W. Vogel of Berlin found that when films were stained with certain dyes and exposed to the spectrum an increased action on development was shown in those parts of the spectrum which the dye absorbed. The dyes which produced this action he called "optical sensitizers," whilst preservatives which absorbed the halogen liberated by light he called "chemical sensitizers." A dye might, according to him, be an optical and a chemical sensitizer. He further claimed that, if a film were prepared in which the haloid soluble salt was in excess and then dyed, no action took place unless some "chemical sensitizer" were present. The term "optical sensitizer" seems a misnomer, since it is meant to imply that it renders the salts of silver sensitive to those regions of the spectrum to which they were previously insensitive, merely by the addition of the dye. The idea of the action of dyes was at first combated, but it was soon recognized that such an action did really exist. Abney showed in 1875 that certain dyes combined with silver and formed true coloured organic salts of silver which were sensitive to light; and Dr Robert Amory went so far as to take a spectrum on a combination of silver with eosin, which was one of the dyes experimented upon by J. Waterhouse, who had closely followed Dr Vogel, and proved that the spectrum acted simply on those parts which were absorbed by the compound. Abney further demonstrated that, in many cases at all events, the dyes were themselves reduced by light, thus acting as nuclei on which the silver could be deposited. He further showed that even when the haloid soluble salt was in excess the same character of spectrum was produced as when the silver nitrate was in excess, though the exposure had to be prolonged. This action he concluded was due to the dye.

Correct Rendering of Colours in Monochrome.—In Plate II., fig. 14, the sensitiveness of a plate stained with homocol is shown, and it is evident that as it is sensitive throughout the visible spectrum there must be some means of cutting off by a transparent screen so much of the spectrum luminosity at different parts that every colour having the same luminosity to the eye shall be shown on a negative of equal density. When this is done the relative luminosities of all colours will be shown by the same relative densities or in a print by different depths of greys. Abney devised a sensitometer which should be used to ascertain the colour of the screen that should be employed. By proper means the luminosity of the light of day coming through a red, a green, a blue and an orange glass can be very accurately measured; if ½-in. squares of these coloured glasses, together with a white glass of the same area, be placed in a row and cemented on white glass, we have a colour-screen which we can make available for finding the kind of light-filter to be employed. This is readily done by reducing the luminosity of the light coming through all the glasses to that of the luminosity of the light coming through the blue glass. If the luminosity of the blue be 5 and that of the white light 100, then the luminosity of the former must be reduced to $\frac{1}{20}$ of its original value, and so with the other glasses. The luminosity of the light coming through each small glass square can be made equal by rotating in front of them a disk in which apertures are cut corresponding to the reduction required. The

blue glass, for instance, would not be covered by the disk at all, while opposite the white square the disk would have an aperture of an angle of 18°. When a plate is exposed behind the row of glass squares, with the light passing through the rotating disk, having the appropriate apertures for each glass, the negative obtained would, under ordinary conditions, show square patches of very different opacity. A light-filter of some transparent colour, if placed in the path of the light, will alter the opacities, and eventually one can be found which will only allow such coloured light to be transmitted as will cause all the opacities in the negative to be the same. As the luminosities of the white light passing through the glasses are made equal, and as the photographic deposits are also rendered equal, this light-filter, if used in front of the camera lens, will render all coloured objects in correct monochrome luminosity. Another plan, based on the same principles, is to place segments of annuluses of vermilion, chrome yellow, emerald green, French blue and white on a disk, and to complete the annuluses with black segments, the amount of black depending on the luminosity of the pigments, which can be readily measured. When the disk is rotated, rings of colour, modified in brightness by black, are seen, and each ring will be of the same luminosity. As before, a screen (light-filter) to be used in front of the lens must be found which will cause the developed images of all the rings to appear of equal opacity. It must be remembered that the light in which the object is to be photographed must be the same as that in which the luminosity of the glasses or pigments is measured.

Action of the Spectrum on Chromic Salts.—The salts most usually employed in photography are the bichromates of the alkalis. The result of spectrum action is confined to its own most refrangible end, commencing in the ultra-violet and reaching as far as in the solar spectrum. Fig. 2 shows the relative action of

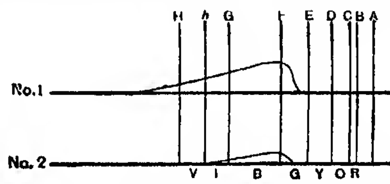

Fig. 2.—The top letters have reference to the Fraunhofer lines; the bottom letters are the initials of the colours. The relative sensitiveness is shown by the height of the curve above the base-line.

the various parts of the spectrum on potassium bichromate. If other bichromates are employed, the action will be found to be tolerably well represented by the figures. No. 1 is the effect of a long exposure, No. 2 of a shorter one. It should be noticed that the solution of potassium bichromate absorbs those rays alone which are effective in altering the bichromate. This change is only possible in the presence of organic matter of some kind, such as gelatin or albumen.

Action of the Spectrum on Asphaltum.—This seems to be continued into and below the red, the blue rays, however, are the most effective. The action of light on this body is to render it less soluble in its usual solvents.

Action of the Spectrum on Salts of Iron.—The commonest ferric salt in use is the oxalate, by which the beautiful platinotype prints are produced. We give this as a representation (fig. 3) of

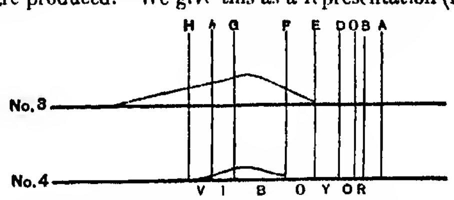

Fig. 3.—Same description as for fig. 2.

the spectra obtained on ferric salts in general. Here, again, we have an example of the law that exists as to the correlation between absorption and chemical action. One of the most remarkable compounds of iron is that experimented upon by Sir J. Herschel and later by Lord Rayleigh, viz. ferrocyanide of potassium and ferric chloride. If these two be brushed over paper, and the paper be then exposed to a bright solar spectrum, action is exhibited into the infra-red region. This is one of the few instances in which these light-waves of low refrangibility are capable of producing any effect. The colour of this solution is a muddy green, and analysis shows that it cuts off these rays as well as generally absorbs those of higher refrangibility.

Action of Light on Uranium.—The salts of uranium are affected by light in the presence of organic matter, and they too are only acted upon by those rays which they absorb. Thus nitrate of uranium, which shows, too, absorption-bands in the green blue, is affected more where these occur than in any other portion of the spectrum.

Some salts of mercury, gold, copper, lead, manganese, molybdenum, platinum, vanadium, are affected by light, but in a less degree than those which we have discussed. In the organic world there are very few substances which do not change by the continuous action of light, and it will be found that as a rule they are affected by the blue end of the spectrum rather than by the red end (see PHOTOCHEMISTRY).

The following table gives the names of the observers of the action of light on different substances, with the date of publication of the several observations. It is nearly identical with one given by Dr Eder in his *Geschichte der Photo-Chemie*.

Effect of Hydrogen Peroxide on Sensitive Plates.—Dr W. J. Russell made a series of experiments on the effect of exposure of sensitive plates to the action of vapours and gases for long periods. It has long been known that contact of plates with such substances as wood caused a sensitive surface to show "fog" on development. By a somewhat exhaustive series of experiments, Russell showed that the probable cause of this fog is hydrogen peroxide, since substances which favoured its formation produced the same effect. This is somewhat remarkable, as this same substance will completely destroy the effect that light has had on a sensitive plate; indeed, it affords one way of destroying a light image on a sensitive collodion plate. The experiments of Russell give a warning to store exposed plates for brief periods. It appears that negatives wrapped in paraffin paper are secure from this danger.

The Application of Photography to Quantitative Measures.—In order to employ photography for the measurement of light it was necessary that some means should be devised by which the opacity of the deposit produced on the development of a plate could be determined. It is believed that in 1874 the first attempt was made by Sir W. Abney to do this. In the *Phil. Mag.* he showed how density could be measured by means of an instrument, the diaphanometer, he had devised, in which transparent

black wedges were used to make matches between the naked light and the same light after passing through the photographic opacity that had to be measured. In 1887, owing to the perfecting of the rotating sectors, which could be made to increase or diminish the apertures at pleasure during its rotation, the measurement of opacities became easy. The Rumford method of comparing the light through the deposit with the naked beam, using the sectors to equalize the illumination, was adopted, the deposit being placed between the light and the screen, the comparison light being a beam reflected from the same light on to the screen.

Owing to the fact that photographic deposit scatters light more or less, the opacities measured by this plan were slightly greater than was shown when such opacities were to be used for contact printing. The final plan adopted by Abney was to place the part of the plate carrying the deposit to be measured behind a screen constructed as above. C D (fig. 4) is a dull black card with an aperture cut in it which may be of any desired shape. This apeture was covered with transparent paper, as was also a portion B, the same size as A, but pasted on the black card itself. Light thrown from behind A would be matched with light thrown on to B from the front when a rod in the path of this last beam was made to prevent this light falling on A. When a portion of a plate bearing a deposit was placed behind and close to A, the light thrown on B had to be diminshed by the sector till the two squares appeared equally bright and the aperture of the sector was noted and compared with that required when the deposit was removed.

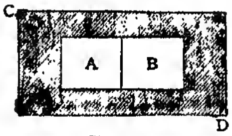

Fig. 4.

With this screen accurate measures of printing densities can be made, and it can also be used in the determination of the comparative photographic brightness of the light issuing from different objects. For instance, the relative brightness of the different parts of the corona as seen in a total eclipse can be readily determined if a "time scale" of gradation is impressed on the plate on which it is taken. Both scale and streamer can then be enlarged optically and thrown on the part of the screen A. The measures of the streamer densities can then be directly compared with the densities of the scale and the relative "photographic" brightness of the different parts of the streamer be ascertained by comparison with this scale also.

The same method of measurement was adopted in ascertaining quantitatively the sensitiveness of the spectrum of ordinary plates and of plates in which dyes are present. Plates I. and II. show reproductions of plates which were exposed to the spectrum. Fig. 8 is a continuous spectrum taken with the electric light; fig. 9 is an impressed continuous spectrum; fig. 10 shows the bright lines of metals; fig. 11 the line spectrum of volatilized lithium and sodium to indicate the position of the spectrum colours. Figs. 12 and 13 are the absorption and fluorescent spectra of eosin. Fig. 14 is the graduation scale formed by a bromogelatin "Seed" plate stained with homocol, a cyanine derivative sensitive to the red; fig. 15 is a similar scale formed by an unstained plate. The small numbers placed below the different bands show an empiric scale which is made to apply to each of them. The first step is to measure

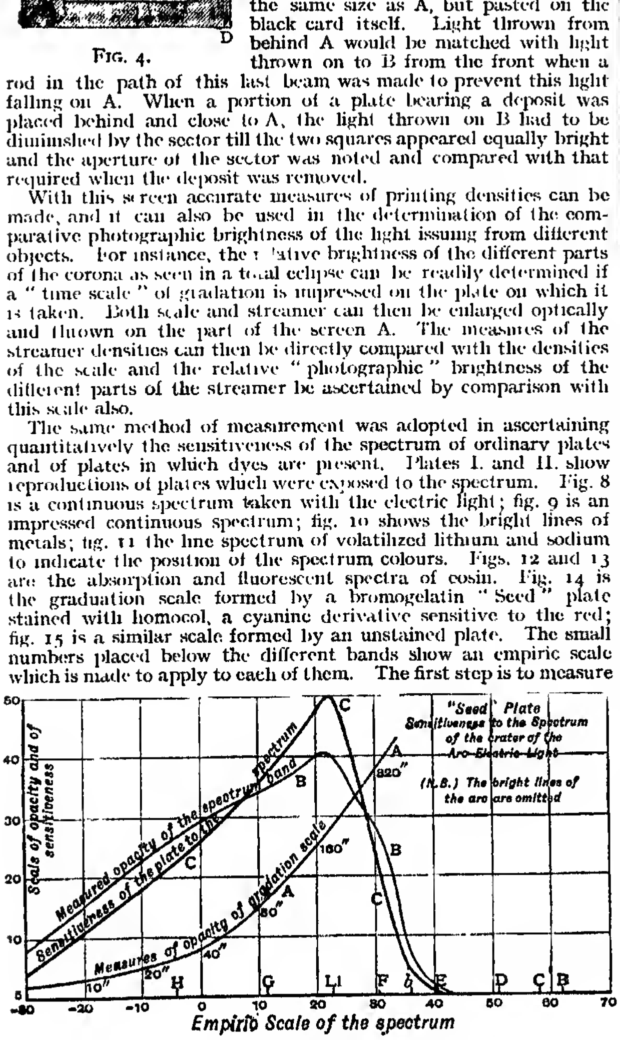

Fig. 5.

the opacity of the gradation scale, next the opacity of the continuous spectrum at the various numbers of the empiric scale, and also the opacity of the other bands at the same scale numbers. The continuous spectrum will give the sensitiveness of the plate to the different parts of the spectrum when the measures of its different opacities are compared with those of the scale of gradation, and a curve of sensitiveness can be plotted from these comparisons. It is evident that the measures of the other two bands will give us information as to the fluorescence and the absorption of the eosin. Fig. 5 shows the curve of opacity of the image of the spectrum at its different parts, and also the curve of sensitiveness of the plate to the different parts of the spectrum. This last is derived from a comparison of the measured densities with those of the gradation scale.

Measurement of the Rapidity of a Plate.—The first attempt that was made to ascertain the rapidity of a plate was by Abney (*Phil. Mag.* 1874), who demonstrated that within limits the transparency of deposit varied as the logarithm of the exposure.

The last formula has been accepted for general use, though it is believed that it is not absolutely correct, though very approximately true and sufficiently near to be of practical value. This belief is based on the further researches described below.[1]

In 1888 Sir W. Abney pointed out that the speed of a plate could be determined by the formula $T = E^{-\mu(\log E+C)^2}$, where T is the transparency, E is the exposure (or time of exposure × intensity of light acting), and C a constant. If the abscissae (exposures) are plotted as logarithms, the curve takes the same form as that of the law of error, which has a singular point, a tangent through which lies closely along the curve and cuts the axis of Y at a point which has a value of $2/\sqrt{E}$. If the total transparency be unity, this ordinate has a value of 1·212, the singular point having a value of 0·606. The ordinate of the zero point of the curve will be where the tangent to the singular point cuts the line drawn at 1·212. The difference between the measurements of this zero point for two kinds of plates (*i.e.* C in the formula) from the points in the abscissae marking the same exposure, will give the relative sensitiveness of the two plates in terms of log a[2]. In 1890 Hurter and Driffield (*Journ. Soc. Chem. Ind.* Jan. 19, 1891) worked out a less empirical formula connecting the exposure E with the density of deposit, which in an approximate shape had the form $D = \gamma \log(E/i)$, where D is the density of deposit (or log 1/T), i the "inertia" of the plate, T the transparency of the deposit. In the customary way a small portion of a plate was exposed to a constant light at a fixed distance and for a fixed time, and another small portion to the same light for double the time, and so on. By measuring the densities of the various deposits and constructing a curve, a large part of which was approximately a straight line, it was found possible, by the production of the straight portion to meet the axis of X, to give the relative sensitiveness of different plates by the distance of the intersection from the zero point I. (See also *Exposure Meters*, below, under § 1, Apparatus.)

Effect of Temperature on Sensitiveness.—In 1876 Abney showed that heat apparently increased, while cold diminished, the sensitiveness of a plate, but the experiments were rather of the qualitative than the quantitative order. In 1893, from fresh experiments,[2] he found that the effect of a difference in temperature of some 40° C. invariably caused a diminution in sensitiveness of the sensitive salt at the lower temperature, a plate often requiring more than double the exposure at a temperature of about −18° C. than it did when the temperature was increased to +33° C. The general deduction from the experiments was that increase in temperature involved increase in sensitiveness so long as the constituents of the plate (gelatin, &c.) were unaltered. Sir James Dewar stated at the Royal Institution in 1896 that at a temperature of −180° C. certain sensitive films were reduced in sensitiveness to less than a quarter of that which they possess at ordinary temperatures. It appears also, from his subsequent inquiry, that when the same films were subjected to the temperature of liquid hydrogen (−252° C.) the loss in sensitiveness becomes asymptotic as the absolute zero is approached. Presumably, therefore, some degree of sensitiveness would still be preserved even at the absolute zero.

Effect of Small Intensities of Light on a Sensitive Salt.[3]—When a plate is exposed for a certain time to a light of given intensity, it is commonly said to have received so much exposure (E). If the time be altered, and the intensity of the light also, so that the exposure (time × intensity) is the same, it was usually accepted that the energy expended in doing chemical work in the film was the same. A series of experiments conducted under differing conditions has shown that such is not the case, and that the more intense the light (within certain limits) the greater is the chemical action, as shown on the development of a plate. Fig. 6 illustrates the results obtained in three cases. The exposure E is the same in all cases. The curves are so drawn that the scale of abscissae

[1] Those *applicable to the correction* of star magnitudes as determined by photography have been verified and confirmed by Schwarzchild, Michalke and others.

[2] Abney, *Proc. Roy. Soc.* 1893.

[3] *Ibid.*, and *Journ. Camera Club*, 1893.

is the intensity of the light in powers of -2, and the ordinates show the percentages of chemical action produced. If the chemical action remained the same when the intensity of light was reduced, E remaining the same, each of the curves would be shown as a straight line at the height of 100, which is the transparency of deposit with the unit of light. As it is, they show diminishing percentages as the light intensity is diminished.

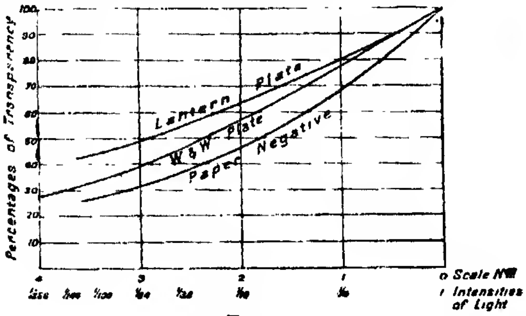

FIG. 6.

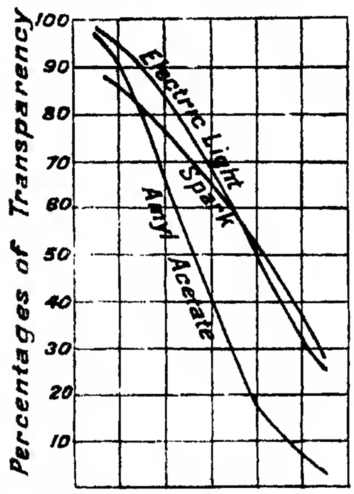
Thus, when the intensity of the light is reduced to $\frac{1}{64}$ of the original, and the time of exposure is prolonged 64 times, the useful energy expended on a lantern plate is only 50 % of that expended when the light and time of exposure are each unity. In the cases to which the diagram refers, the light used was a standard amyl acetate lamp, and the unit of intensity taken was this light at a distance of 2 ft. from the plate, and the unit of time was 10 seconds. The lamp being moved to 16 ft. from the plate, gave an intensity of $\frac{1}{64}$ the unit, and the time of exposure had to be increased to 640 seconds, so that E was the same in both cases. Further, it was found that when the *times* of exposure on different parts of the plate were successively doubled, light at a fixed distance being used for one series, and altered for a second series, the slopes of the curves of transparency (*i.e.* the gradation) were parallel to one another. This investigation is of use when camera images are in question, as the picture is formed by different intensities of light, not very different from those of the amyl acetate lamp, the *time of exposure* being the same for all intensities. The deductions made from the investigation are that with a slow plate the energy expended in chemical action is smaller as the intensity is diminished, while with a quick plate the variation is much less. As a practical deduction, we may say that to obtain proper contrast in a badly lighted picture it is advisable to use a slow plate.



Scale of Intensities in Powers of 2

FIG. 7.

Effect of very Intense Light on a Sensitive Salt.—Another investigation was made as to the effect of very intense light on sensitive surfaces. In this case a screen of step-by-step graduated opacities was made use of, and plates exposed through it to the action of lights markedly differing in intensity, one being that of the amyl acetate lamp, another that of the arc light, and a third the light emitted from the spark of a Wimshurst machine. The exposures were so made that one of the opacities produced on the plate from exposure to each source of light was approximately the same. The unit of intensity of light is, of course, in each case widely different. The slope of the curve due to the spark light is less steep than that due to the arc light, and the latter, again, is much less steep than that due to the amyl acetate lamp. A further investigation was made of the effect of increasing the time of exposure when the intense light was diminished, and it was found that with all plates the useful chemical energy acting on a plate was least with the most intense light, but increased as the intensity diminished, though the time was correspondingly increased. This is the reverse of what we have recorded as taking place when a comparatively feeble light was employed. Further, it was proved that the variation was greatest in those plates which are ordinarily considered to be the most rapid. It follows, therefore, that there is some intensity of light when the useful chemical energy is at a maximum, and that this intensity varies for each kind of plate.

Intermittent Exposure of a Sensitive Salt.—The same investigator has shown that, if a total exposure is made up of intermittent exposures, the chemical action on a sensitive salt is less than it is when the same exposure is not intermittent. It was also proved that the longer the time of rest between the intermittent exposures (within limits) the less was the chemical action. We may quote one case. Exposures were first made to a naked light, and afterwards to the same light for six times longer, as a rotating disk intervened which had 12 apertures of 5° cut in it at equal intervals apart, and 720 intermittent exposures per second were given. The plate was moved to different distances from the light, so that the intensity was altered. The apparent loss of exposure by the intervention of the disk increases as the intensity diminishes, the ratios of the chemical energy usefully employed of the naked light exposure to that of the intermitting exposures being: –

For intensity	1	1 to ·815
„ „	$\frac{1}{4}$	1 „ ·500
„ „	$\frac{1}{16}$	1 „ ·423
„ „	$\frac{1}{64}$	1 „ ·370

These results appear to be explicable by the theoretical considerations regarding molecular motion.

Effect of Monochromatic Light of Varying Wave-lengths on a Sensitive Salt.—It has been a subject of investigation as to whether the gradation on a plate is altered when exposures are made to lights of different colours; that is to say, whether the shades of tone in a negative of a white object illuminated by, say, a red light, would be the same as those in the negative if illuminated by a blue light. Abney[1] announced that the gradation was different; and, quite independently, Chapman Jones made a general deduction for isochromatic plates that. except with a certain developer, the gradation was steeper (that is, the curve shown graphically would be steeper) the greater the wave-lengths of the light to which the sensitive salt was subjected. For plates made with the ordinary haloid salts of silver Chapman Jones's deduction requires modification. When monochromatic light from the spectrum is employed, it is found that the gradation increases with wave-lengths of light which are less, and also with those which are greater, than the light whose wave-lengths has a maximum effect on the sensitive salt experimented with. Thus with bromo-iodide of silver the maximum effect produced by the spectrum is close to the blue lithium line, and the gradation of the plate illuminated with that light is less steep than when the light is spectrum violet, green, yellow or red. From the red to the yellow the gradation is much the steepest. Whether these results have any practical bearing on ordinary photographic exposures is not settled, but that they must have some decided effect on the accuracy of three-colour work for the production of pictures in approximately natural colours is undoubted, and they may have a direct influence on the determination of star magnitudes by means of photography.

Reproduction of Coloured Objects by Means of Three Photographic Positives.—Ives's Process.—A practical plan of producing images in approximately the true colours of nature has been devised by preparing three positives of the same object, one

[1] *Proc. Roy. Soc.* 1900.

illuminated by a red, the other by a green, and the third by a blue light; the images from these three transparencies, when visually combined, will show the colours of the object. This plan was scientifically and practically worked out by F. E. Ives of Philadelphia, though in France and elsewhere it had been formulated, especially by Hauron Du Cros.

The following description may be taken as that of Ives's process: by the trichromatic theory of colour-vision every colour in nature can be accounted for by the mixture of two or three of the three-colour sensations, red, green and blue, to which the eye is supposed to respond. Thus a mixture of a red and green sensation produces the sensation of yellow; of a green and blue, that of a blue-green; of red and blue, that of purple; and of all three, that of white. For the sensations we may substitute those colours which most nearly respond to the theoretical sensations without any material loss of purity in the resulting sensation. We must take the spectrum of white light as the only perfect scale of pure colours. It has been proved that the red sensation in the eye is excited by a large part of the visible spectrum, but with varying intensities. If, then, we can on a photographic plate produce a developed image of the spectrum which exactly corresponds in opacity and position to the amount of red stimulation excited in those regions, we shall, on illuminating a transparent positive taken from such a negative with a pure red light, have a representation of the spectrum such as would be seen by an eye which was only endowed with the sensation of red. Similarly, if negatives could be taken to fulfil the like conditions for the green and for the blue sensations, we should obtain positives from them which, when illuminated by pure green and blue light respectively, would show the spectrum as seen by an eye which was only endowed with a green or a blue sensation. Evidently if by some artifice we can throw the coloured images of these three positives on a screen, superposing them one over the other in their proper relative positions, the spectrum will be reproduced, for the overlapping colours, by their variation in intensity, will form the colours intermediate between those used for the illumination of the positives. For the purpose of producing the three suitable negatives of the spectrum, three light-filters, through which the image has to pass before reaching the photographic plate, have to be found. With all present plates these are compromises. Roughly speaking, the screens used for taking the three negatives are an orange, a bluish-green and a blue. These transmit those parts of the spectrum which answer to the three sensations. When these are obtained an image of a coloured object can be reproduced in its true colours.

Abney devised sensitometers for determining the colours of the screens to be placed before the lens in order to secure the three-colour negatives which should answer these requirements. Their production depends upon the same principles indicated as necessary for the correct rendering in monochrome of a coloured object. When the sensitometer takes the form of glasses through which light is transmitted to the plate, the luminosities of the coloured lights transmitted are determined, and also their percentage composition in terms of the red, green, and blue lights, and thence are deduced the luminosities in terms of red, green and blue. For ascertaining what screen should be used to produce the red negative the luminosity transmitted through each glass is so adjusted that the luminosity of the red components in each is made equal by rotating a disk with correct apertures cut out close to the row of glasses. This gives a sensitometer of equal red values. A coloured screen has to be found which, when placed in front of the lens, will cause the opacities of the deposit on the plate, corresponding to each square of glass, to be the same throughout. This is done by trial, the colour being altered till the proper result is obtained. In a similar way the "green" and "blue" screens are determined. Coloured pigments rotating on a disk can also be employed, as indicated in the paragraph on the correct rendering of colour in monochrome.

As to the camera for the amateur, whose plates are not as a rule large, all of the three negatives should be obtained on one plate, since only in this way can they be developed and the densities increased together. (For commercial work the negatives often cannot be taken on the same plate, as it would make the plate too large to manipulate.) The camera may be of an ordinary type, with a repeating back, bringing successively three different portions of the plate opposite the lens. It is convenient to have a slide, in front of which a holder containing the three screens can be fixed, which will then be close to the plate; such a one has been devised by E. Sanger-Shepherd. The light passes through them one by one as the plate is moved into the three positions. The three exposures are given separately, after which the plate is ready for development. The three separate exposures are, however, a source of trouble at times, particularly in the case of landscapes, for the lighting may vary and the sky may have moving clouds, in which case the pictures would show variations which should not exist. Sanger-Shepherd has a "one-exposure" camera by which the three images are thrown side by side on the plate. Thus any movement in the picture affects all three negatives alike. Abney has also introduced a "one-exposure" camera which takes in a larger angle than that of Sanger-Shepherd. The next point is the exposures which should be given through each screen. This can be done by placing in front of the plate and extending its whole length a scale of gradation through which the light coming from a sun-illuminated white card passes, as well as through the screens. In the case of the three-exposure camera the *times* of exposure are varied till the densities of the image of the gradation appear the same in each of the three images. In the case of the one-exposure camera, the light reaching the plate through the screens is altered by cutting off with a shutter more or less of the lens used. As the plates employed for the purpose of the three-colour negatives must be sensitive to every colour, the ordinary dark-room light should be most cautiously used. If used at all, it should be very feeble and development must be carried out in a dish with a cover to it. The plate is manipulated in the usual way.

Joly's Process.—Professor J. Joly, of Dublin, in 1897 introduced a colour process by which an image in approximately natural colours could be thrown upon a screen by an optical lantern, only one transparency being employed, instead of three, as in the Ives process. A "taking" screen was ruled with alternating orange, blue-green and blue lines $\frac{1}{200}$ to $\frac{1}{300}$ in. apart, touching one another and following one another in the above order. When such a screen was placed in front of a sensitive plate in the camera, and exposure made to the image of a coloured object, there were practically three negatives on the same plate, each being confined to the area occupied by lines of the same colour. The shades of colour and the depth of the colours used in ruling depended on the brand of plate. When a perfect triune negative was obtained, a transparency was made from it, and in contact with this was placed a screen ruled with lines the same distance apart, but of the colours corresponding to the three colour sensations, namely red, green and blue. The red lines were made to fall on the image taken through the orange lines, the green on that of the blue-green, and the blue or violet on that of the blue. On the screen there are practically three differently coloured images shown by one transparency. The eye blends the different colours together and a picture is seen in approximately the correct colours of the original.

Autochrome.—A very remarkable process, founded on J. Joly's process, was introduced in 1907 by A. Lumière et ses Fils of Lyons. Starch grains of very minute size, some of which were dyed with a red stain, a second portion with a green, and a third portion with a blue, are mixed together in such proportions that a fine layer of them appears grey when viewed by transmitted light. Under a magnifying glass the grains are coloured, but owing to the want of focus in the eye the colours blend one with the other. Such a layer is embedded on the surface of a glass plate in a waterproof vehicle, and a film of sensitive emulsion held *in situ* in some material, the composition of which has not been published, covers this layer. When such a plate is placed in the camera, with *the back of the plate* next the lens, the light passes through he coloured granules, and again we have three negatives on one plate, but instead of each negative being represented by lines as in the Joly process they are represented by dots of silver deposit. Owing to the way in which the three-coloured film is prepared, it is evident that a positive taken from such a negative could not be backed with granules of the right colour, as the granules are placed at random in the layer. Lumière, to overcome this difficulty, converted the negative into a positive in a very ingenious way. The plate was developed with pyrogallic and ammonia in the usual way, but instead of fixing it it was plunged into a solution of potassium permanganate and sulphuric acid. This dissolved all the silver that had been deposited during development and left a film of unaltered silver salt. On looking through the plate the colours of the coloured layer coming through the different dots where the silver was at

first deposited appeared in view, and the image was the image in colour of the object photographed. The plate after being washed was taken into the light and redeveloped with an alka line developer, which converted the sensitive salt of silver to the metallic state. The image now consisted of black particles of silver and the coloured image. The plate was next fixed in hyposulphite of soda to remove any unreduced silver salt that might be left, and the picture after washing was complete. The coloured image so obtained is a very close representation of the true colours, but as the "taking" screen is the same as the "viewing" screen some little variation must result.

Positives in Three Colours.—Ives was the first to show that a transparency displaying approximately all the colours in nature could be produced on the same principles that underlie the three-colour printing. This he effected by printing each of the three negatives, produced for his triple projection process as already described, on gelatine films sensitized by bichromate of potash. Each of the three transparent fiims was dyed with a colour complementary to the colour of the light which he transmitted through the positives when used for projection. Thus the "red" positive he dyed with a blue-green dye, the "green" positive with a purple dye, and the "blue" positive with a yellow dye. These three films, when superposed, gave the colours of the original object. Sanger-Shepherd has made the process a commercial success (see PROCESS) and produces lantern slides of great beauty, in which all colours are correctly rendered. Instead of using a dye for the "red" transparency, he converts the silver image of a positive image into an iron salt resembling Prussian blue in colour. (W. DE W. A.)

II.—PHOTOGRAPHIC APPARATUS

Photographic apparatus consists essentially of the camera with lens and stand, lens shutters, exposure meters, prepared plates for the production of negatives or transparencies, sensitive papers and apparatus for producing positive prints, direct or by enlargement. Besides these there are many subsidiary accessories.

Since the introduction of highly sensitive dry plates and their extended use in hand cameras, the art and practice of photography have been revolutionized. Numerous special forms of apparatus have been created suitable for the requirements of the new photography, and their manufacture and sale have become important industries. The value of the exports of photographic materials from the United Kingdom in 1906 was £22,716. The most important improvement has been in the construction of anastigmatic lenses, which, having great covering power, flatness of field, and freedom from astigmatism, can be worked with very much larger apertures than was possible with the earlier forms of rectilinear or aplanatic lenses. The increased rapidity of working thus gained has rendered it easy to photograph objects in very rapid motion with great perfection. This has encouraged the construction of the very light and compact hand cameras now so universally in use, while, again, their use has been greatly simplified by improvements in the manufacture of sensitive plates and films and the introduction of light, flexible, sensitive films which can be changed freely in daylight. The introduction in 1907 of Messrs Lumiere's "Autochrome" process of colour photography has also been a great advance, tending to popularize photographic work by the facility it offers for reproducing objects in the colours of nature.

The Camera.

Historical.—The camera obscura (*q.v.*) was first applied to photographic use by Thomas Wedgwood between 1792 and 1802. No description of his camera is available, but it was probably one of the sketching cameras then in use. In 1812 W. H. Wollaston found that by using a meniscus lens with a concave surface towards the object and the convex towards the screen, a diaphragm being placed in front, the projected image of the camera obscura was greatly improved in sharpness over a larger field. The first photographic lenses made by V. and Ch. L. Chevalier in Paris (1830–1840) were on this principle. The photographic camera in its simplest form is a rectangular box, one end of which is fitted to carry a lens and the opposite one with a recess for holding the focusing screen and plate holders, these ends being connected by a rigid or expanding base-board and body, constructed to keep out all light from the sensitive plate except that passing through the lens. In 1816 Joseph Nicéphore Niepce, of Chalon-sur-Saône, for his photographic experiments made a little camera, or artificial eye, with a box 6 in. square fitted with an elongated tube carrying a lenticular glass. There are now in the Chalon Museum cameras of his with an iris diaphragm for admitting more or less light to the lens; some with an accordion bellows, others with a double expanding rigid body for adjusting the focus. The iris diaphragm was adopted later by Chevalier for his photographic lenses. In 1835 W. H. Fox Talbot constructed simple box cameras for taking views of his house on sensitive paper, and claimed them as the first photographs of a building (*Phil. Mag.* 1839, 14, p. 206). Fr. von Kobell and C. A. Steinheil, early in 1839, made a camera with an opera glass lens for taking landscapes on paper. Later in 1839 J. W. Draper successfully used a camera for his daguerreotype experiments made of a spectacle lens, 14 in. focus, fitted into a cigar box. He also used a camera fitted with a concave mirror instead of a lens. Similar cameras were constructed by A. T. Wolcott (1840) and R. Beard (1841) for reversing the image in daguerreotype portraits. They have also been recommended by V. Zenger (1875) and D. Mach (1890) for scientific work.

L. J. M. Daguerre's camera, as made by Chevalier in 1839 for daguerreotype, was of Niepce's rigid double body type, fitted with an achromatic meniscus lens with diaphragm in front on Wollaston's principle, the back part with the plate moving away from the lens for focusing, and fixed in its place with a thumbscrew. This expanding arrangement enabled lenses of different focal lengths to be used. With modifications cameras of this type were in use for many years afterwards for portrait and studio purposes. For work in the field they were found inconvenient, and many more portable forms were brought out, among them G. Knight's and T. Ottewill's single and double folding cameras (1853), made collapsible with hinges, so as to fold on to the base-board. Cameras with light bodies made of waterproof cloth, &c., also came into use, but these were superseded by cameras with collapsible bellows-body of leahter, which, invented by Niepce, were used in France, in 1839, by Baron A. P. de Séguier and others for daguerreotype. The first record of them in England is, apparently, J. Atkinson's portable stereoscopic camera of parallel-side bellows form (*Ph. Journ.* 1857, 3, p. 261), which was soon followed by C. T. H. Kinnear's lighter conical form, made by Bell of Edinburgh (*Ph. Journ.* 1858, 4, p. 166). They have since been made in various patterns, conical, oblong and square, by P. Meagher, G. Hare and others, and are still, in modified forms, in general use as studio, field or hand cameras. When wet collodion plates were used many cameras were fitted with arrangements for developing in the field.

Information on these and other early cameras will be found in the photographic journals, in C. Fabre's *Traité encyclopédique de photographie*, vol. i., and in J. M. Eder's *Ausfuhrliches Handbuch der Photographie*, 2nd ed., vol. i., pt. ii.

The distinctive feature of present-day photography is the world-wide use of the hand camera. Its convenience, the ease with which it can be carried and worked, and the remarkably low prices at which good, useful cameras of the kind can be supplied, concurrently with improvements in rapid sensitive plates and lenses, have conduced to this result. It has also had a valuable educational influence in quickening artistic perception and scientific inquiry, besides its use in depicting scenes and passing events for historical record. Small portable cameras had been made by B. G. Edwards (1855), T. Scaife (Pistolgraph, 1858), A. Bertsch (1860), T. Ottewill (1861), and others, but it was not until rapid gelatin dry plates were available in 1881 that T. Bolas brought out his "detective" camera (*Ph. Journ.* 1881, p. 59). It consisted of a double camera (one as finder, the other for taking the picture) enclosed in another box, suitably covered, which also contained the double-plate carriers and had apertures

in front of the viewing and taking lenses. In another form the finder was omitted. A month later A. Loisseau and J. B. Germeuil-Bonnaud patented an opera glass camera. Various forms of portable magazine cameras followed, among them A. Pumphrey's "Repeating Camera" (1881), W. Rouch's "Eureka" (1887), R. Krugener's camera (book form, 1888), and others in collapsible or box forms disguised as books, watches, &c., but they did not come into general use before 1888, when the Eastman Company of Rochester, U.S.A., brought out their very portable roll-film cameras, now known under the trade name of "Kodak." The manufacture of these and other light hand cameras has since become a very important and flourishing industry in Great Britain, Germany, France and the United States. It is noteworthy that the most modern form of hand camera, the reflex, goes back to an early type of portable camera obscura, figured by Johann Zahn in 1686, in which a mirror was used for reflecting the image on to a horizontal focusing screen, at the same time reversing it. The first photographic camera on this principle was T. Sutton's (1860), which has served as a basis for many subsequent developments. A. D. Loman's (1889) and R. Krugener's (1891) were early examples of the hand camera type, but great improvements have since been made.

Modern cameras differ so much in details of improved construction that only a few of the more important requirements can be noticed. A camera should be well and strongly made of seasoned wood or of metal, perfectly rigid when set up, to avoid any shifting of the axis of the lens in respect to the sensitive plate. The front and back of the camera should normally be vertical and parallel, and the axis of the lens perpendicular to the centre of the plate, but arrangements are usually made by vertical and lateral adjustments on the camera front for raising the lens to take in less foreground or vice versa, or for moving it right or left, the latter becoming a vertical movement when the camera has to be turned on its side. In the Adams "Idento" camera the lens and finder can be rotated together on the rising front according as the camera is used horizontally or vertically, the finder showing in either case the identical view projected on the plate. The best modern field cameras are fitted with a swing-back or swing-front and sometimes with both. A swing-back is necessary for bringing back the plate to the vertical position, so as to prevent convergence of vertical lines, when the camera has to be tilted. A rising swing-front, in which the lens is tilted, answers the same purpose, provided the camera is kept level. If further tilting is necessary, when taking high buildings &c., the swing-back and front may both be required, but must be kept vertical and parallel and the effect is that of an abnormal rising front. Many modern cameras are fitted with a double rising front. The vertical and side swings are also useful for equalizing the definition of objects at different distances from the camera, but they alter the perspective. These swing-movements should preferably be round the central horizontal or vertical axis of the back or front, but are frequently effected by simple inclination of the back or lens front on a hinge. When the rising front is used a lens of extended covering power is desirable, and it may be necessary to stop it down to obtain good definition over the extended area of the picture. A slight inclination of the lens may also be useful in readjusting the focus. The camera and plate carriers must be perfectly light-tight and all inner bright surfaces made dead black to prevent reflections from bright spots being thrown on the plate. The black varnish used, preferably of shellac and lampblack in spirit, must have no deleterious effect on the plates. Although the weight and bulk are increased it is convenient to have the camera square and fitted with a reversible back, so that the greatest length of the plate may be horizontal or vertical, as desired. Many cameras are fitted with revolving backs to be used in either position. In some French cameras the back part of the camera with the bellows is reversible, to be used upright or horizontal.

Focusing.—The earlier cameras were focused by drawing out the back and clamping it with a thumb-screw working in a slot in the base-board. When bellows cameras were introduced they were focused by an endless screw, and these are still used for large copying cameras. Most modern cameras are fitted with rack and pinion movements working either in front or at the back of the camera or both. Many hand cameras, requiring to be brought to focus at once, are fitted with studs (infinity catches) which fix the front in focus for distant objects, nearer distances being noted on an engraved scale attached to the base-board. Such scales should be verified by measurement. In hand cameras with fixed infinity focus, the necessary adjustments for distance of near objects are made on the lens mount. The focusing screen may be ruled with parallel cross lines for purposes of measurement, and as a check on the verticality of the camera when photographing buildings or other objects with vertical lines. The distance of the lens from the focusing screen and from the sensitive plate in the dark slide must coincide exactly. This can be tested by measurement or by focusing a bright, well-defined object on the screen and then on a ground-glass plate placed in each of the slides to be examined. A level or other means of showing that the camera is level and the plate vertical should be attached to the camera, also a view meter or finder, showing the exact extent of the picture on the focusing glass. In the view meter the picture is viewed directly through a pin-hole mounted at the back of the camera as it appears in a frame with cross wires on the rising front, adjusted to the size of the plate and the focus of the lens. Finders are practically small reflex cameras, and a reduced image is seen reflected from a mirror or prism. A rectangular concave glass mounted on the camera is also a convenient form, it can be combined with a mirror for vertical observation, and in Watson's new form is also arranged as a level and telemeter (*B. J. A.* p. 724, 1908). The image seen in the finders should correspond exactly with that on the plate. When the rising front is used special arrangements have to be made to ensure the correspondence of the images in the finder and on the ground-glass. This is done in the "Adams Identoscope" (1908), which is fitted to the swing front and adjusted by a lever to follow the movement of the lens.

Plate-holders or Dark-slides.—The dark-slides or backs, holding sensitive plates, are made either single or double, the former usually for wet plates, the latter for dry plates. The ordinary book-form double dark-slide has been in use since the early days of calotype paper negatives, and contains two plates separated by a blackened metal plate; three of them usually form a set, the shutters being numbered 1 to 6, the odd numbers on the opening side. Inner frames can be used for smaller plates if desired. The slides should fit easily into the camera and the shutters run smoothly out and in. They must be perfectly light-tight, the corner joints, the hinges in the shutters, and the openings in the sides and top of the book-form slides are all weak points requiring occasional careful examination or protection by metal plates. The shutters of dark-slides are either jointed or solid and removable; the former is perhaps the more convenient, but both forms may become liable to let in light. Various forms of solid slides, single and double, are now made in wood or metal, or of wood for the frame and metal for the shutters; they are lighter, more compact and less liable to admit light to the plates. In some cases one slide can suffice for the exposure of several plates or stiff films, enclosed in separate envelopes, as in the "Wishart-Mackenzie" slide, the "Victrix" and other similar ones, or contained in a single packet, as in the "Premo Filmpack," and similar arrangements which enable twelve thin celluloid films to be placed in the camera, exposed one after the other, and removed again safely in daylight, the pack being replaced, if necessary, by another. The packets of films are made of light cardboard, and effect a great saving of bulk and weight (fig. 1). Roll-holders are also a convenient way of carrying sensitive celluloid films in lengths of six or twelve exposures, rolled on spools, which can be changed in daylight. Changing boxes for holding a reserve of plates or celluloid films in sheaths, are used with some magazine and other cameras. They are arranged to fit on the camera in place of the dark-slide and the plates are changed automatically so that exposed plates are placed in order successively at the back, a fresh plate going forward for exposure and the number of the exposure being recorded at the same time.

Fig. 1.—Premo Filmpack.

Studio cameras, for portraiture, are usually of the square bellows type, of solid construction, to take large and heavy lenses; adjustable from front and back with rack and pinion movements, to enable long or short focus lenses to be used, with extra extension for copying or enlarging. They are generally fitted with repeating backs, allowing two or more exposures to be made on one plate. The backs are square or reversible, so that the plates can be used upright or lengthways, and are fitted with double swing movements at the back. When single dark slides are used they are best fitted with a flexible shutter to avoid jerking and movement of the camera. For portraiture they are mounted on solid pillar stands, being raised or lowered with an endless screw or rack-work, and the table-top usually has vertical and horizontal angular movements. Large cameras with long extension for copying purposes are made in many forms with special arrangements for the various photo-mechanical processes, and are mounted on substantial table-stands with screw adjustments for obtaining the various motions above noted, and also a rectilinear traversing motion right or left. All these stands should be absolutely rigid and free from tremor. Process cameras are, however, sometimes mounted,

first deposited appeared in view, and the image was the image in colour of the object photographed. The plate after being washed was taken into the light and redeveloped with an alkaline developer, which converted the sensitive salt of silver to the metallic state. The image now consisted of black particles of silver and the coloured image. The plate was next fixed in hyposulphite of soda to remove any unreduced silver salt that might be left, and the picture after washing was complete. The coloured image so obtained is a very close representation of the true colours, but as the "taking" screen is the same as the "viewing" screen some little variation must result.

Positives in Three Colours.—Ives was the first to show that a transparency displaying approximately all the colours in nature could be produced on the same principles that underlie the three-colour printing. This he effected by printing each of the three negatives, produced for his triple projection process as already described, on gelatine films sensitized by bichromate of potash. Each of the three transparent fims was dyed with a colour complementary to the colour of the light which he transmitted through the positives when used for projection. Thus the "red" positive he dyed with a blue-green dye, the "green" positive with a purple dye, and the "blue" positive with a yellow dye. These three films, when superposed, gave the colours of the original object. Sanger-Shepherd has made the process a commercial success (see PROCESS) and produces lantern slides of great beauty, in which all colours are correctly rendered. Instead of using a dye for the "red" transparency, he converts the silver image of a positive image into an iron salt resembling Prussian blue in colour. (W. DE W. A.)

II.—PHOTOGRAPHIC APPARATUS

Photographic apparatus consists essentially of the camera with lens and stand, lens shutters, exposure meters, prepared plates for the production of negatives or transparencies, sensitive papers and apparatus for producing positive prints, direct or by enlargement. Besides these there are many subsidiary accessories.

Since the introduction of highly sensitive dry plates and their extended use in hand cameras, the art and practice of photography have been revolutionized. Numerous special forms of apparatus have been created suitable for the requirements of the new photography, and their manufacture and sale have become important industries. The value of the exports of photographic materials from the United Kingdom in 1906 was £22,716. The most important improvement has been in the construction of anastigmatic lenses, which, having great covering power, flatness of field, and freedom from astigmatism, can be worked with very much larger apertures than was possible with the earlier forms of rectilinear or aplanatic lenses. The increased rapidity of working thus gained has rendered it easy to photograph objects in very rapid motion with great perfection. This has encouraged the construction of the very light and compact hand cameras now so universally in use, while, again, their use has been greatly simplified by improvements in the manufacture of sensitive plates and films and the introduction of light, flexible, sensitive films which can be changed freely in daylight. The introduction in 1907 of Messrs Lumiere's "Autochrome" process of colour photography has also been a great advance, tending to popularize photographic work by the facility it offers for reproducing objects in the colours of nature.

The Camera.

Historical.—The camera obscura (*q.v.*) was first applied to photographic use by Thomas Wedgwood between 1792 and 1802. No description of his camera is available, but it was probably one of the sketching cameras then in use. In 1812 W. H. Wollaston found that by using a meniscus lens with a concave surface towards the object and the convex towards the screen, a diaphragm being placed in front, the projected image of the camera obscura was greatly improved in sharpness over a larger field. The first photographic lenses made by V. and Ch. L. Chevalier in Paris (1830–1840) were on this principle. The photographic camera in its simplest form is a rectangular box, one end of which is fitted to carry a lens and the opposite one with a recess for holding the focusing screen and plate holders, these ends being connected by a rigid or expanding base-board and body, constructed to keep out all light from the sensitive plate except that passing through the lens. In 1816 Joseph Nicéphore Niepce, of Chalon-sur-Saône, for his photographic experiments made a little camera, or artificial eye, with a box 6 in. square fitted with an elongated tube carrying a lenticular glass. There are now in the Chalon Museum cameras of his with an iris diaphragm for admitting more or less light to the lens; some with an accordion bellows, others with a double expanding rigid body for adjusting the focus. The iris diaphragm was adopted later by Chevalier for his photographic lenses. In 1835 W. H. Fox Talbot constructed simple box cameras for taking views of his house on sensitive paper, and claimed them as the first photographs of a building (*Phil. Mag.* 1839, 14, p. 206). Fr. von Kobell and C. A. Steinheil, early in 1839, made a camera with an opera glass lens for taking landscapes on paper. Later in 1839 J. W. Draper successfully used a camera for his daguerreotype experiments made of a spectacle lens, 14 in. focus, fitted into a cigar box. He also used a camera fitted with a concave mirror instead of a lens. Similar cameras were constructed by A. T. Wolcott (1840) and R. Beard (1841) for reversing the image in daguerreotype portraits. They have also been recommended by V. Zenger (1875) and D. Mach (1890) for scientific work.

L. J. M. Daguerre's camera, as made by Chevalier in 1839 for daguerreotype, was of Niepce's rigid double body type, fitted with an achromatic meniscus lens with diaphragm in front on Wollaston's principle, the back part with the plate moving away from the lens for focusing, and fixed in its place with a thumbscrew. This expanding arrangement enabled lenses of different focal lengths to be used. With modifications cameras of this type were in use for many years afterwards for portrait and studio purposes. For work in the field they were found inconvenient, and many more portable forms were brought out, among them G. Knight's and T. Ottewill's single and double folding cameras (1853), made collapsible with hinges, so as to fold on to the base-board. Cameras with light bodies made of waterproof cloth, &c., also came into use, but these were superseded by cameras with collapsible bellows-body of leahter, which, invented by Niepce, were used in France, in 1839, by Baron A. P. de Séguier and others for daguerreotype. The first record of them in England is, apparently, J. Atkinson's portable stereoscopic camera of parallel-side bellows form (*Ph. Journ.* 1857, 3, p. 261), which was soon followed by C. T. H. Kinnear's lighter conical form, made by Bell of Edinburgh (*Ph. Journ.* 1858, 4, p. 166). They have since been made in various patterns, conical, oblong and square, by P. Meagher, G. Hare and others, and are still, in modified forms, in general use as studio, field or hand cameras. When wet collodion plates were used many cameras were fitted with arrangements for developing in the field.

Information on these and other early cameras will be found in the photographic journals, in C. Fabre's *Traité encyclopédique de photographie*, vol. i., and in J. M. Eder's *Ausfuhrliches Handbuch der Photographie*, 2nd ed., vol. i., pt. ii.

The distinctive feature of present-day photography is the world-wide use of the hand camera. Its convenience, the ease with which it can be carried and worked, and the remarkably low prices at which good, useful cameras of the kind can be supplied, concurrently with improvements in rapid sensitive plates and lenses, have conduced to this result. It has also had a valuable educational influence in quickening artistic perception and scientific inquiry, besides its use in depicting scenes and passing events for historical record. Small portable cameras had been made by B. G. Edwards (1855), T. Scaife (Pistolgraph, 1858), A. Bertsch (1860), T. Ottewill (1861), and others, but it was not until rapid gelatin dry plates were available in 1881 that T. Bolas brought out his "detective" camera (*Ph. Journ.* 1881, p. 59). It consisted of a double camera (one as finder, the other for taking the picture) enclosed in another box, suitably covered, which also contained the double-plate carriers and had apertures

ingenious devices have been invented for effecting the change (fig. 5). Some forms are effective and popular on account of their compactness and readiness for immediate exposure, but there is always a risk of the mechanism failing, and care has to be taken in charging them to lay the plates truly in their places. The very handy binocular cameras, or *photo-jumelles*, of which the "Vérascope" (fig. 6) is a type, are of this class, and have additional

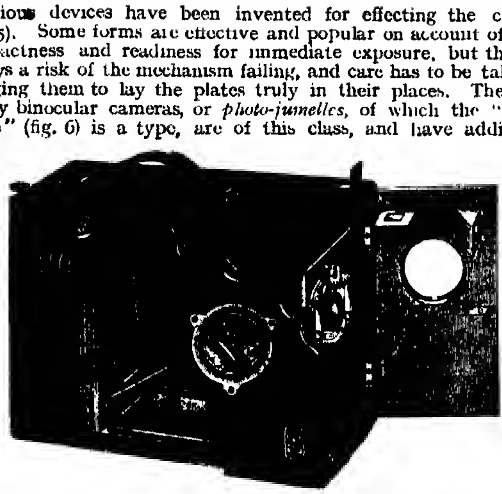


FIG. 7.—Beck's Dai-Cornex Daylight-loading Camera.

magazines. So also are hand cameras of R. and J. Beck's "Frena" type, specially constructed for using stiff celluloid films. The films are notched on two sides and packed in bundles alternately with cards similarly notched. The pack of films and cards is placed in a magazine at the back of the camera, and by the movement of a lever, after exposure, the exposed film and its following card are released, and by turning the camera down are dropped into a second receptacle. A "folding Frena" is now made as a folding camera with attached magazine for films, without which it can be used separately for plates. R. and J. Beck's new "Dai-Cornex" is a great improvement in this form of camera, being a daylight-loading box magazine camera for plates, the plates being packed in a bundle of ridged sheaths, so that they are quite protected from light and can be put into or taken out of the camera in full daylight. In other respects it resembles other magazine cameras (fig. 7). Another useful magazine camera is the "Zambex," carrying either plates or films, held in skeleton frames in envelopes which can be loaded or unloaded in daylight, and are kept ready for use in the back of the camera and exposed consecutively. For work in which speed is of primary importance hand cameras fitted with very rapid lenses and focal plane shutters are necessary, and several forms of portable collapsible cameras of this kind are now available, such as the Goerz-Anschütz, Zeiss's "Palmos," Watson's "Vril" (fig. 8), Adams' "Idento," &c., and are lighter and more portable than the reflex cameras. Hand cameras are generally fitted with screw-bushes for mounting on a tripod stand when time exposures are wanted. The light folding wooden or aluminium stands noted below are specially suitable.

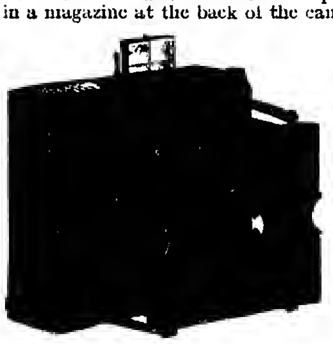

FIG. 8.—Watson's "Vril" Camera.

Twin-lens and Reflex Cameras.—For photographing animals, objects in motion, public functions, &c., it is important to have the means of watching the movement till the critical moment of exposure arrives. For this it is convenient to have a camera fitted with twin lenses working in two separate compartments (fig. 9) or more simply with a mirror throwing a full-sized unreversed image of the object from the lens on to the focusing screen (fig. 10.) With the former, which has the advantage that the image is seen before, during, and after exposure, the lenses must be of exactly equal focus and focused together by the same motion of the rack-work, the object being viewed on the focusing screen of the upper compartment, and the plate kept ready in the lower to be exposed when desired. Binocular hand cameras are also made on this principle, one compartment serving for focusing, the other holding lens and plates. Stereoscopic cameras are another form of twin-lens cameras, and are usually made for also taking single panoramic pictures.

I, Plate.

In *reflex* cameras only one lens is necessary, though two are convenient, and can be used somewhat as in fig. 9. They generally consist of a cubical box camera containing a movable mirror facing the lens at an angle of 45° and throwing up the image projected from it on to a horizontal focusing screen, on which it is viewed through a flexible hood which folds down in the upper part of the camera when not in use (fig. 10). In order to get the greatest rapidity of exposure a focal-plane shutter is generally fitted, and by a single movement of the release the mirror is smoothly lifted and the plate exposed simultaneously. They should be fitted with anastigmatic lenses working at large apertures for very rapid work. In some forms the lens is fixed, but usually there is a front bellows extension for long focus lenses, with rising and falling front, to which swing motion may be given, a swing-back not being generally used with the focal plane shutter. In the "Ernex" camera E. Human has made an arrangement by which the camera back, horizontal viewing screen and reflector are made to swing simultaneously, by a rack and pinion movement. They may also have reversing or revolving backs for quickly changing the position of the plate. 5 in. × 4 in. and $3\frac{1}{4}$ in. × $4\frac{1}{4}$ in. are the usual sizes of the plates, but larger and smaller sizes are also available. These cameras require the best workmanship and perfect mechanism for successful working and freedom from any jarring movement in releasing the shutter or mirror. The focusing screen must also be in accurate register with the focus of the lens on the plate. Those forms in which the image can also be viewed at the height of the eye, as in the Graflex (fig. 10), are preferable. Although reflex cameras are rather heavy and bulky as hand cameras, they have many advantages over the ordinary hand camera with finder and focusing scales for the purpose of the press photographer, the naturalist and others, in observing and recording very rapid movements, and have come into very general use for such purposes. They permit the accurate focusing of a full-sized image on the ground glass up to the moment of exposure, especially useful when lenses of long or short focus are required and when the rising or swing front is in use. The aspect of this image on the ground-glass is also a great aid in the selection and placing of the subject and in judging the exposure required for it. They practically have all the advantages of a stand camera and can be used as such on a stand for subjects requiring prolonged exposure. They are also coming into increasing use in studio work for portraits of children, &c. Their use and adjustments are discussed by G. E. Brown in the ***British Journal Almanac*** for 1909.

Panoramic Cameras.—Many so-called "panoramic" cameras have been introduced from time to time, among them T. Sutton's (1861), and J. R. Johnson's "Pantascopic" (1864), but did not come into general use till the use of curved surfaces of celluloid film enabled such cameras of convenient size and weight to be put on the market. They are on the same principle as one made by F. von Martens in 1845 for curved daguerreotype plates, and covering an angle of 150°. P. Moëssard's "Cylindrographe" of 1889 was the first of the modern type. It consists of a semicircular

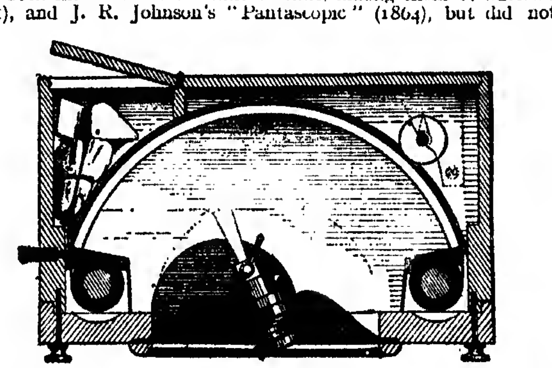

FIG. 11.—Section of "Al-Vista" Panoramic Camera.

camera, the front of it formed of light-proof cloth and the back by the curved flexible carriers. The lens is fitted on a vertical axis, so that the nodal point of emergence remains motionless, and is revolved round it by means of a handle worked by hand and carrying a view meter. The illumination of the image is regulated by an adjustable vertical slit in a tube attached to the lens inside the box, and by altering the rate at which the lens is revolved. The pictures taken embrace less than 180°. The apparatus folds together and is quite portable; it is fully described in Moessard's *Le Cylindrographe* (Paris, 1889). The "Al-Vista" (1901) and the "Panoram Kodak" (1900) are on the same principle, but arranged as roll-holder hand cameras, in two sizes, carrying film for several exposures, 7 in. × 2¼ in. or 4 in. × 12 in. They work instantaneously, and by means of a clock-spring the lens rotates rapidly over a half-circle when released. The angle of view is about 120° (figs. 11 and 12). The views taken with this kind of camera are sometimes disappointing, on account of the development of cylindrical perspective on a plane surface causing apparent distortion. This distortion is avoided in Carl Zeiss's "Palmos Panoram" camera for plates 6¾ in. × 3½ in., fitted with "Tessar" lens and focal plane shutter, and other similar cameras which can be used for stereoscopic or single pictures. Other more elaborate instruments driven by clockwork have been made for making a complete tour of the horizon. Among them C. Damoizeau's "Cyclographe," which can be used with lenses of different foci and takes the pictures on a roll-film, which is unrolled as the instrument revolves on its axis, the lens also rotating on its nodal point of emergence; and thus the image always remains sharp (*Bull. Soc. Franc. d. Phot.*, 1891, p. 183,). Commandant A. Daubresse has improved on Moëssard's apparatus, by placing the lens vertically between two right-angled prisms, the upper of which receives the image and projects it through the lens on to the lower prism, from which, by rotation of the system on the vertical axis, it is projected on to a cylindrical film through an angle of 360° (ibid. 1906, p. 430; *E. Jb.*, 1907, p. 91). The "Periphote" and Ernemann's "Rundblick" camera are improved forms (*E. Jb.*, 1908, p. 322).

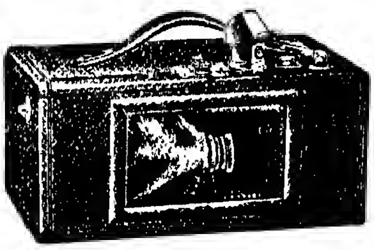

FIG. 12.—"Al-Vista" Panoramic Camera, closed.

Many early forms of panoramic cameras are described in *B. J. A.*, 1892, p. 517. Colonel R. W. Stewart's "Panoram" (1893), A. Chevalier's "Photographic Plane Table," J. Bridges Lee's "Photo-Theodolite" (1894), and similar cameras fitted with telescopes, levels and divided circles, are instruments of precision suitable for photographic surveying. Improved instruments for topographical surveying with stereo-photographic apparatus, on the principle worked out by Dr C. Pulfrich, of Messrs Zeiss & Co., in his stereo-comparator (1903), are being practically developed, and much information regarding them will be found in papers by E. Dolezal and others in J. M. Eder's *Jahrbucher*, 1903 to 1908; also a papor by Lieut. F. V. Thompson in *Geographical Journal*, 1908, xxxi. 534.

Cameras for Three-Colour Photography.—Many forms of camera have been constructed for making the three negatives required for trichromatic photography. They fall into two types: (1) those with a repeating back fitted with three colour-screens or filters—red, green and violet—through which the colour impressions are made successively with one lens upon a single colour-sensitive plate, as in the Sanger-Shepherd system. The colour-screens are placed immediately in front of the sensitive plate in the repeating back, which is moved on for each exposure. In a more recent form, by the same maker, the three images are taken on the sensitive plate with one exposure. The camera is divided into three compartments, and fitted with a special diaphragm which can be regulated for the varying sensitiveness of different batches of plates. The central image is impressed directly on the plate; the other two by reflection from prisms arranged so as to equalize the sizes of the three images on the sensitive plates, the light rays passing in each case through a suitable colour-filter—red, green and blue-violet—somewhat on the principle of F. E. Ives's camera of 1900 (fig. 13). It is convenient and successful in working. (2) Cameras made on the reflecting principle of L. Ducos du Hauron (1876), elaborated by F. E. Ives (1894) in his photochromoscope, in which three images are taken through three colour-screens on separate plates with one lens, the respective exposures being regulated by reflection of the light coming from the lens by plane mirrors on to the sensitive plates, and its filtration through the colour-screens in front of them. Many variations of this method have been proposed, in which reflecting prisms replace the mirrors. The different systems have been discussed by W. Gamble (*Ph. Journ.* 1905, xlv. 150), the latter also by E. T. Butler (ibid. p. 199). Sir W. de W. Abney has described three-colour cameras for landscape work in *Ph. Journ.* 1904, xliv. 81, and 1908, xlviii. 331.

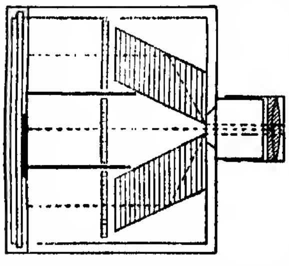

FIG. 13.—Diagram of Camera for Three-colour Photography.

Enlarging Cameras.—These cameras vary in form, according to the nature of the illumination, but ordinarily consist of a double or triple extension bellows camera, with a holder for the negative or transparency at one end, and for the sensitive plate or paper at the other, the lens being placed on a fixed partition between the two. Some recent forms of "daylight enlargers" can be used as an ordinary camera. Other cheaper ones are on the fixed focus principle. Enlargers for use with artificial light are made like a magic lantern, with a condenser, projecting an enlarged image on to a sensitive plate or paper fixed on an easel or screen. A simple arrangement for daylight enlarging is to fix a suitable camera on to a larger one by a sliding front, and mount the two on a studio stand tilted so that the image may be illuminated by the open sky.

Cinematographs.—Many special cameras and lenses have been introduced for taking on a long flexible sensitive film an extended series of small photographs of the successive phases of movements, and again projecting them on a screen so as to reproduce the scene, with an illusion of motion, in what are known as "living pictures," biographs, &c. As each photograph requires a certain minimum time for exposure and must be kept in true position in sequence with the rest, some means of regulating the intermittent exposures and keeping the film in position have to be adopted; and there are many different ways of doing it, either by a continuous or intermittent motion and exposure of the film while it is being unwound from one roller on to another. The films used are similar to the ordinary celluloid films, but in narrow bands from 1⅜ in. to 2⅝ in. in width, the length varying with the number of exposures required, at the the rate of 16 to 20 per second. They are perforated on both sides, so that they may run true and have the necessary intermittent motion, the perforations fitting on to studs on a sprocket wheel in connexion with the driving wheel and crank handle. Special lenses of short focus, from 1 in. to 3 in., with good covering power and large apertures $f/4$ to $f/2$, are required both for photographing and projecting; several such are noted below. Absolute rigidity in the camera is essential. Special stands are made for the purpose, but if a tripod stand is used it should be well braced. Special apparatus is required for developing and fixing the exposed films. They are wound on large rollers supported over troughs containing the necessary solutions (see CINEMATOGRAPH). The mechanical arrangements are treated in H. V. Hopwood, *Living Pictures* (1899); F. P. Liesegang, *Handbuch der praktischen Kinematographie* (1907); K. W. Wolf-Czapek, *Die Kinematographie* (1908); G. Lindsay Johnson, *Photographic Optics* (1909); Eder's *Jahrbucher*.

A method of cinematography in colour was introduced by G. A. Smith and C. Urban in 1908, the main features of it being the use of a film sensitive to *all* colour waves to the furthest red; superimposing the colour records by persistence of vision; the use of two-colour records instead of three, in order to reduce the interval between the successive presentations; adaptation to existing cinematograph machinery and films. These conditions are fulfilled by the use, in place of the ordinary revolving sector shutter in front of the lens passing intermittent white light, of a special, more rapidly revolving shutter divided into four sectors, one fitted with orange-red glass, another with bluish-green glass and two intermediate opaque sectors, so that at every revolution of the shutter an exposure is made through the red and green glasses alternately. The former passes white and yellow, and then orange, scarlet to deepest red; whilst the latter also passes white and yellow, green, blue-green, blue, all in proportion according to the red and green sensitiveness of the specially sensitized panchromatic emulsion on the film. The same shutter and colour screens are used for projection, somo supplementary blue rays being added. The results are satisfactory and the method promises to be of great practical value (see *Journ. Roy. Soc. Arts*, 1908, 57, No. 2926).

Special cameras are made for various branches of scientific research in photo-micrography, photo-spectroscopy, astronomical photography, &c.

Tripod Stands.—Field cameras are usually supported on wooden tripod stands, folding in two or more sections, the head being separate or fixed in the base-board of the camera. The legs should be capable of extension to about 5 ft. and adjustable in length for use on uneven ground. A tripod stand may be light, but must be firm and rigid when set up. To prevent slipping, shoes of india-rubber or cork may be fitted to the points of the legs, and in some cases it may be desirable to strengthen the tripod by a folding adjustable brace. W. Butler's "Swincam" camera stand is made to enable the camera to be securely fixed in awkward positions, and has many valuable special features, great extension, swivel points to the feet, &c. For hand cameras the very light, portable metal folding and walking-stick stands are convenient.

Photographic Objectives or Lenses.

The objective is the most important item of photographic apparatus, because upon it depends the perfection with which a correct and well-defined picture is projected upon the *plane* surface of the sensitive plate of objects in the different planes forming the field of view, which naturally would come to a locus on a series of *curved* surfaces. This flattened picture must be equally illuminated and sharply defined, within a limit of confusion from $\frac{1}{100}$ to $\frac{1}{250}$ of an inch, over a sufficiently wide angle. A good objective must also pass sufficient light to produce the required effect on the photographic plate with short exposures; the chemical and visual foci must coincide exactly, and it must not distort straight or parallel lines. The fulfilment of these conditions is complicated by the presence of sundry focal displacements or aberrations. (1) *Spherical aberration*, or non-coincidence of the foci of the central and marginal pencils of rays passing through the lens. It is corrected by varying the curves of the component lenses and by the use of a diaphragm. (2) *Coma*, or blur, due to lateral spherical aberration of oblique rays, and mostly found in unsymmetrical combinations and single view lenses. It is partly eliminated by the diaphragm. (3) *Astigmatism*, which accompanies coma in single lenses, and is usually present in symmetrical aplanats, manifests itself by forming two sets of images of points off the axis, lying in two separate curved surfaces, one set focusing tangentially as more or less horizontal lines, the other radially as more or less vertical lines. It increases with the obliquity of the rays and causes want of definition and difference of focus between horizontal and vertical lines away from the centre. (4) *Curvature of field*, also increasing with the obliquity of the rays. (5) *Distortion*, outward or inward, according to the nature and construction of the objective. With the single meniscus view lens, used with its concave surface towards the object and a diaphragm in front, a square will appear barrel-shaped from inward contraction of the lines towards the centre; but with the convex surface towards the object and the diaphragm behind, it will appear with concave sides from outward expansion from the centre. It can be corrected by using two such lenses with the convex sides outwards and a central diaphragm, as in periscopic or rectilinear lenses. Lenses of the orthoscopic and telephoto types generally show the latter form of distortion. (6) *Chromatic aberration*, produced by the dispersion of the white light passing through the lens, and the different coloured rays composing it coming to a focus at different distances from the visual focus in the order of their wave-lengths. It thus affects both the *positions* and *sizes* of the image for the different colours. For ordinary photographic work it suffices for the blue-violet and yellow rays to be coincident, but for the new processes of photography in three colours, apochromatic lenses, in which perfect coincidence of the coloured rays is secured, are required to obtain the accurate register of the three images. The corrections are effected by compensating lenses of different refractive powers (See ABERRATION.)

In constructing photographic objectives these aberrations and distortions have to be neutralized, by regulating the curves of the different positive and negative component lenses, the refractive and dispersive indices of the glasses from which they are made, and the distances of the refracting surfaces, so as to make the objective as far as possible *stigmatic* or focusing to a *point*, giving an image well defined and undistorted. This perfect correction could never be effected in objectives made before 1887, and very few could be effectively used at their full apertures, because although linear distortion could be overcome there were always residual aberrations affecting the oblique rays and necessitating the use of a diaphragm, which by lengthening out the rays caused them to define clearly over a larger surface, at the expense of luminous intensity and rapidity of working. The introduction of rapid gelatin dry plates enabled photographs to be taken with much greater rapidity than before, and led to a demand for greater intensity of illumination and better definition in lenses to meet the requirements of the necessarily very rapid exposures in hand cameras. For studio and copying work quick-acting lenses are also valuable in dull weather or in winter.

The rapidity of a lens with a light of given intensity depends upon the diameter of its aperture, or that of the diaphragm used, relatively to the focal length. In order, therefore, to obtain increased rapidity combined with perfect definition, some means had to be found of constructing photographic objectives with larger effective apertures. This necessity had long been recognized and met by many of the best makers for objectives of the single meniscus and aplanatic types, but with only partial success, because such objectives are dependent upon the diaphragm for the further correction necessary to obtain good definition over an extended field. The difficulty was in the removal of astigmatism and curvature of the field, which, as J. Petzval had shown, was impossible with the old optical flint and crown glasses. In 1886 Messrs E. Abbe and O. Schott, of Jena, introduced several new varieties of optical glasses, among them new crown glasses which, with a lower dispersion than flint glass, have a *higher* instead of a *lower* refractive power. It was thus rendered possible to overcome the old difficulties and to revolutionize photographic optics by enabling objectives to be made free from astigmatism, working at their full apertures with great flatness of field independently of the diaphragm, which is now chiefly used to extend the area of definition or angle of view, and the so-called "depth of focus" for objects in different planes.

Photographic objectives may be classed as follows:—

1. Single achromatic combinations. 2. Unsymmetrical doublets. 3. Symmetrical doublets. 4. Triple combinations.	Old types.
5. Anastigmatic combinations—symmetrical and unsymmetrical. 6. Telephotographic objectives. 7. Anachromatic combinations.	New types.

They are also sometimes classified according to their rapidity, as expressed by their effective apertures, into "extra rapid," with apertures larger than *f*/6; "rapid," with apertures from *f*/6 to *f*/8; "slow," with apertures less than *f*/11. Another classification is according to the angle of view, "narrow angle" up to 35°; "medium angle" up to 60°; "wide angle" up to 90°, 100°, or more. Many lenses are made in series, differing in rapidity and angle of view as well as in length of focus.

1. *Single Achromatic Combination or Landscape Lens.*—This is the earliest form of photographic objective, evolved from W. H. Wollaston's improved single periscopic meniscus camera obscura lens (1812). It was made achromatic by Ch. Chevalier, and so used by L. J. M. Daguerre, though it required correction for chemical focus, as did the object glasses of telescopes or opera glasses first used for photography. The single landscape lens usually consists of an achromatic compound meniscus, formed of a biconvex positive crown cemented to a biconcave negative flint to secure achromatism and partially correct the spherical aberration, and may be taken as the type of the "old photographic achromat" (fig. 14).[1] It is used with its concave side towards the object and a diaphragm in front, thus producing inward or barrel-shaped distortion, inherent in this type of objective, and rendering it unsuitable for copying or architecture, though not very noticeable in landscape work. The full aperture has to be largely reduced by a diaphragm to improve definition; so it is slow, though many improved forms have been brought out. It has always been popular for pure landscape work on account of the equality of illumination over the plate, depth of focus, and the softness and brilliancy of the image owing to its thinness and freedom from reflecting surfaces. In some of its improved and "long focus" forms it is preferred by portraitists for large heads, on account of the general softness it gives when used with large apertures.

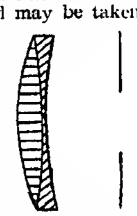

FIG. 14.–Single Landscape Lens.

The following are some of the best-known improved objectives of this type: T. Grubb's "Aplanatic" (1857), *f*/15 to *f*/30 (fig. 15); J. H. Dallmeyer's "Wide Angle Landscape Lens" (1865), *f*/15, angle 75°. In it distortion was reduced and marginal definition improved. The "Rapid (long focus) Landscape Lens" (1884), *f*/12, angle 40° (fig. 16), was a modification of it, and at *f*/8 is useful for heads in portraiture. W. Wray's "Landscape Lens" (1886), *f*/11, is also useful for portraiture in the larger sizes at *f*/8. Fr. Voigtländer's "Wide-Angle Landscape Lens" (1888)

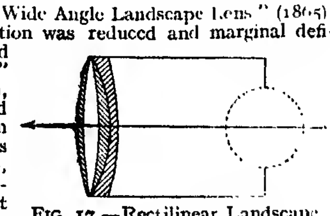

FIG. 17.—Rectilinear Landscape Lens.

[1] In the diagrams of lenses which follow, a uniform system of indicating the nature of the glass employed by means of the shading has been adopted.

Flint glass is indicated thus:—

Crown glass of low refractive power thus:—

Crown glass of high refractive power thus:—

(These two are used indiscriminately in lenses made before the introduction of the new Jena glass.)

Extra light flint glass thus:—

In most cases the front of the lens is on the right.

camera, the front of it formed of light-proof cloth and the back by the curved flexible carriers. The lens is fitted on a vertical axis, so that the nodal point of emergence remains motionless, and is revolved round it by means of a handle worked by hand and carrying a view meter. The illumination of the image is regulated by an adjustable vertical slit in a tube attached to the lens inside the box, and by altering the rate at which the lens is revolved. The pictures taken embrace less than 180°. The apparatus folds together and is quite portable; it is fully described in Moessard's *Le Cylindrographe* (Paris, 1889). The "Al-Vista" (1901) and the "Panoram Kodak" (1900) are on the same principle, but arranged as roll-holder hand cameras, in two sizes, carrying film for several exposures, 7 in. × 2¼ in. or 4 in. × 12 in. They work instantaneously, and by means of a clock-spring the lens rotates rapidly over a half-circle when released. The angle of view is about 120° (figs. 11 and 12). The views taken with this kind of camera are sometimes disappointing, on account of the development of cylindrical perspective on a plane surface causing apparent distortion. This distortion is avoided in Carl Zeiss's "Palmos Panoram" camera for plates 6¾ in. × 3½ in., fitted with "Tessar" lens and focal plane shutter, and other similar cameras which can be used for stereoscopic or single pictures. Other more elaborate instruments driven by clockwork have been made for making a complete tour of the horizon. Among them C. Damoizeau's "Cyclographe," which can be used with lenses of different foci and takes the pictures on a roll-film, which is unrolled as the instrument revolves on its axis, the lens also rotating on its nodal point of emergence; and thus the image always remains sharp (*Bull. Soc. Franc. d. Phot.*, 1891, p. 183,). Commandant A. Daubresse has improved on Moëssard's apparatus, by placing the lens vertically between two right-angled prisms, the upper of which receives the image and projects it through the lens on to the lower prism, from which, by rotation of the system on the vertical axis, it is projected on to a cylindrical film through an angle of 360° (ibid. 1906, p. 430; *E. Jb.*, 1907, p. 91). The "Periphote" and Ernemann's "Rundblick" camera are improved forms (*E. Jb.*, 1908, p. 322).

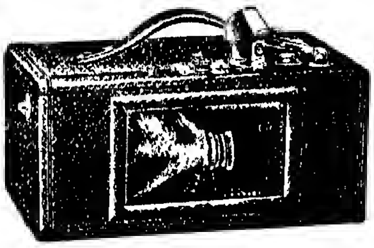

FIG. 12.—"Al-Vista" Panoramic Camera, closed.

Many early forms of panoramic cameras are described in *B. J. A.*, 1892, p. 517. Colonel R. W. Stewart's "Panoram" (1893), A. Chevalier's "Photographic Plane Table," J. Bridges Lee's "Photo-Theodolite" (1894), and similar cameras fitted with telescopes, levels and divided circles, are instruments of precision suitable for photographic surveying. Improved instruments for topographical surveying with stereo-photographic apparatus, on the principle worked out by Dr C. Pulfrich, of Messrs Zeiss & Co., in his stereo-comparator (1903), are being practically developed, and much information regarding them will be found in papers by E. Dolezal and others in J. M. Eder's *Jahrbucher*, 1903 to 1908; also a paper by Lieut. F. V. Thompson in *Geographical Journal*, 1908, xxxi. 534.

Cameras for Three-Colour Photography.—Many forms of camera have been constructed for making the three negatives required for trichromatic photography. They fall into two types: (1) those with a repeating back fitted with three colour-screens or filters—red, green and violet—through which the colour impressions are made successively with one lens upon a single colour-sensitive plate, as in the Sanger-Shepherd system. The colour-screens are placed immediately in front of the sensitive plate in the repeating back, which is moved on for each exposure. In a more recent form, by the same maker, the three images are taken on the sensitive plate with one exposure. The camera is divided into three compartments, and fitted with a special diaphragm which can be regulated for the varying sensitiveness of different batches of plates. The central image is impressed directly on the plate; the other two by reflection from prisms arranged so as to equalize the sizes of the three images on the sensitive plates, the light rays passing in each case through a suitable colour-filter—red, green and blue-violet—somewhat on the principle of F. E. Ives's camera of 1900 (fig. 13). It is convenient and successful in working. (2) Cameras made on the reflecting principle of L. Ducos du Hauron (1876), elaborated by F. E. Ives (1894) in his photochromoscope, in which three images are taken through three colour-screens on separate plates with one lens, the respective exposures being regulated by reflection of the light coming from the lens by plane mirrors on to the sensitive plates, and its filtration through the colour-screens in front of them. Many variations of this method have been proposed, in which reflecting prisms replace the mirrors. The different systems have been discussed by W. Gamble (*Ph. Journ.* 1905, xlv. 150), the latter also by E. T. Butler (ibid. p. 199). Sir W. de W. Abney has described three-colour cameras for landscape work in *Ph. Journ.* 1904, xliv. 81, and 1908, xlviii. 331.

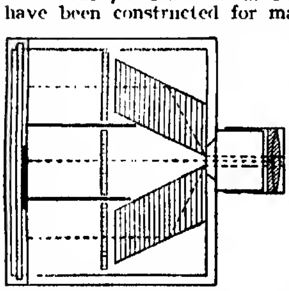

FIG. 13.—Diagram of Camera for Three-colour Photography.

Enlarging Cameras.—These cameras vary in form, according to the nature of the illumination, but ordinarily consist of a double or triple extension bellows camera, with a holder for the negative or transparency at one end, and for the sensitive plate or paper at the other, the lens being placed on a fixed partition between the two. Some recent forms of "daylight enlargers" can be used as an ordinary camera. Other cheaper ones are on the fixed focus principle. Enlargers for use with artificial light are made like a magic lantern, with a condenser, projecting an enlarged image on to a sensitive plate or paper fixed on an easel or screen. A simple arrangement for daylight enlarging is to fix a suitable camera on to a larger one by a sliding front, and mount the two on a studio stand tilted so that the image may be illuminated by the open sky.

Cinematographs.—Many special cameras and lenses have been introduced for taking on a long flexible sensitive film an extended series of small photographs of the successive phases of movements, and again projecting them on a screen so as to reproduce the scene, with an illusion of motion, in what are known as "living pictures," biographs, &c. As each photograph requires a certain minimum time for exposure and must be kept in true position in sequence with the rest, some means of regulating the intermittent exposures and keeping the film in position have to be adopted; and there are many different ways of doing it, either by a continuous or intermittent motion and exposure of the film while it is being unwound from one roller on to another. The films used are similar to the ordinary celluloid films, but in narrow bands from 1⅜ in. to 2⅜ in. in width, the length varying with the number of exposures required, at the the rate of 16 to 20 per second. They are perforated on both sides, so that they may run true and have the necessary intermittent motion, the perforations fitting on to studs on a sprocket wheel in connexion with the driving wheel and crank handle. Special lenses of short focus, from 1 in. to 3 in., with good covering power and large apertures $f/4$ to $f/2$, are required both for photographing and projecting; several such are noted below. Absolute rigidity in the camera is essential. Special stands are made for the purpose, but if a tripod stand is used it should be well braced. Special apparatus is required for developing and fixing the exposed films. They are wound on large rollers supported over troughs containing the necessary solutions (see CINEMATOGRAPH). The mechanical arrangements are treated in H. V. Hopwood, *Living Pictures* (1899); F. P. Liesegang, *Handbuch der praktischen Kinematographie* (1907); K. W. Wolf-Czapek, *Die Kinematographie* (1908); G. Lindsay Johnson, *Photographic Optics* (1909); Eder's *Jahrbucher*.

A method of cinematography in colour was introduced by G. A. Smith and C. Urban in 1908, the main features of it being the use of a film sensitive to *all* colour waves to the furthest red; superimposing the colour records by persistence of vision; the use of two-colour records instead of three, in order to reduce the interval between the successive presentations; adaptation to existing cinematograph machinery and films. These conditions are fulfilled by the use, in place of the ordinary revolving sector shutter in front of the lens passing intermittent white light, of a special, more rapidly revolving shutter divided into four sectors, one fitted with orange-red glass, another with bluish-green glass and two intermediate opaque sectors, so that at every revolution of the shutter an exposure is made through the red and green glasses alternately. The former passes white and yellow, and then orange, scarlet to deepest red; whilst the latter also passes white and yellow, green, blue-green, blue, all in proportion according to the red and green sensitiveness of the specially sensitized panchromatic emulsion on the film. The same shutter and colour screens are used for projection, some supplementary blue rays being added. The results are satisfactory and the method promises to be of great practical value (see *Journ. Roy. Soc. Arts*, 1908, 57, No. 2926).

Special cameras are made for various branches of scientific research in photo-micrography, photo-spectroscopy, astronomical photography, &c.

Tripod Stands.—Field cameras are usually supported on wooden tripod stands, folding in two or more sections, the head being separate or fixed in the base-board of the camera. The legs should be capable of extension to about 5 ft. and adjustable in length for use on uneven ground. A tripod stand may be light, but must be firm and rigid when set up. To prevent slipping, shoes of india-rubber or cork may be fitted to the points of the legs, and in some cases it may be desirable to strengthen the tripod by a folding adjustable brace. W. Butler's "Swincam" camera stand is made to enable the camera to be securely fixed in awkward positions, and has many valuable special features, great extension, swivel points to the feet, &c. For hand cameras the very light, portable metal folding and walking-stick stands are convenient.

improvement was effected in the construction of non-distorting objectives of fairly large aperture. It consisted of two positive cemented flint menisci, each composed of a dense flint with negative focus outside and a light flint with positive focus inside, its concave surfaces facing the centre (fig. 26). This use of flint glasses alone was peculiar, former achromatic lenses having been made of flint and crown. These lenses were made in three rapidities: "Ordinary," *f*/6 or *f*/7, angle 60°; "Landscape," *f*/12 to *f*/15, angle 90°, also used in convertible sets; "Wide Angle Landscape," *f*/20 to *f*/25, angle 104°; "Wide Angle Reproduction," similar to the last, but with sharper definition. The "Aplanat" had many advantages over previous doublets and the triplet, being more rapid, perfectly symmetrical, so that there was no necessity for turning them when enlarging, and free from distortion or flare. There was no chemical focus. Each component could be used alone for landscape work with double focus, subject to the ordinary defects of single lenses. By the use of Jena glasses in the "Universal Aplanat" (1886) the components of this lens were brought closer together, its intensity increased, and it was made more portable. J. H. Dallmeyer had been working in the same direction simultaneously with Steinheil, and in 1866 brought out his "Wide Angle Rectilinear," *f*/15, angle 100°, made of flint and crown, the front element being larger than the back (fig. 27). It was slow for ordinary purposes and was succeeded in 1867 by the well-known "Rapid Rectilinear," *f*/8, on the same

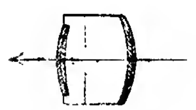

FIG. 27. Wide-Angle Rectilinear Lens.

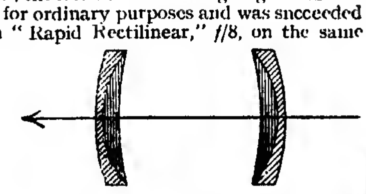

FIG. 28.—Rapid Rectilinear Lens.

principle as Steinheil's "Aplanat," but made of flint and crown (fig. 28). Ross's "Rapid" and "Portable Symmetrical" lenses, Voigtländer's "Euryscopes," and other similar lenses of British and foreign manufacture are of the same type, and still in use. They are excellent for general purposes and copying, but astigmatism is always present, and although they can be used with larger apertures than the triplets they displaced, they require stopping down to secure good marginal definition over the size of plate they are said to cover. By the use of Jena glasses they have been improved to work at larger apertures, and some are made with triple cemented elements.

4. *Triple Combinations: Old Types.*—This class comprises objectives composed of three separate combinations of glasses widely separated from each other. An early form of this type was made by Andrew Ross (1841) for W. H. Fox Talbot, others by F. S. Archer, J. T. Goddard (1859), T. Sutton (1860), but they never came into general use. J. H. Dallmeyer's "Triple Achromatic Lens" (1861), *f*/10, angle 60°, now out of date, was an excellent non-distorting lens, very useful for general work and copying (fig. 29). As made by Dallmeyer, the inner surfaces of the front and back components were slightly concave, but in T. Ross's "Actinic Triplets" (1861), *f*/16, they were flat. The centre lens was an achromatic negative serving to flatten the field.

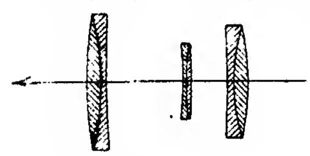

FIG. 29.—Triple Achromatic Lens.

5. *Anastigmatic Combinations, Symmetrical and Unsymmetrical.*—As already stated, it was found practically impossible to obtain flatness of field, together with freedom from astigmatism, in objectives constructed with the old optical glasses. A. Steinheil attempted it in the "Antiplanets," but with only partial success. The Abbe and Schott Jena glasses, issued in 1886, put a new power into the hands of opticians by largely increasing their choice of glasses with different refractive and dispersive powers. Whereas the old glasses had high refractivity with higher dispersion, in the new ones high refractivity with lower dispersion could be set against lower refractivity with higher dispersion.

Between 1887 and 1889 the first attempts to make anastigmatic objectives with the new glasses were made by M. Mittenzwei of Zwickau, R. D. Gray of New Jersey, E. Hartnach and A. Miethe of Berlin ("Pantoscope"), K. Fritsch of Vienna ("Apochromat") and Fr. von Voigtländer of Brunswick, with more or less success, but progress was hindered by the instability of some of the early glasses, which was afterwards overcome by sandwiching the soft glasses between two hard ones. In 1888 Dr H. L. H. Schroeder worked out for Messrs Ross the "Concentric Lens" (fig. 30) issued in 1892 (*Ph. Jour.*, 16, p. 276). It was a symmetrical doublet of novel construction, each element consisting of a plano-convex crown of high refractivity cemented to a plano-concave flint of lower refractivity, but about equal or higher dispersion. Both the uncemented surfaces were spherical and concentric. At *f*/16 it gave sharp definition and flatness of field with freedom from astigmatism, distortion or flare over an angle of 75°. It was an excellent lens, though slow, and has been superseded by the "Homocentric" and other more rapid anastigmats. Dr Paul Rudolph, of Messrs Carl Zeiss & Co., Jena, worked out in 1889 a new and successful method of constructing a photographic objective by which astigmatism of the oblique rays and the want of marginal definition due to it could be

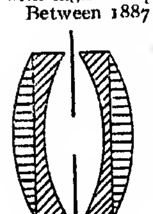

FIG. 30.—Concentric Lens.

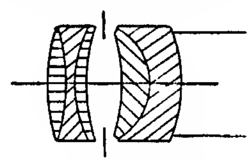

FIG. 31.—Anastigmat. Series II. *f*/6·3.

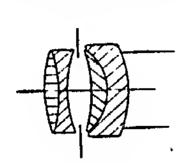

FIG. 32.—Anastigmat. Series III*a*. *f*/9.

eliminated without loss of rapidity, so that a comparatively extended field could be covered with a large aperture. This he did on the principle of the opposite or opposed gradation of the refractive indices in the front and back lenses, by a combination of two dissimilar systems of single lenses cemented together, the positive element in each having in one case a *higher* and in the other a *lower* refractive index than that of the negative element with which it was associated. The front system, relied upon for the correction of spherical aberration, was made of the old glasses, a crown positive of low and a flint negative of high refractivity, whilst the back system, relied upon for the anastigmatic flattening of the field, was made of the new glasses, a crown positive of high and a flint negative of low refractivity. Both systems being spherically and chromatically corrected for a large aperture, the field was flattened, the astigmatism of the one being corrected by the opposite astigmatism of the other, without destroying the flatness of the field over a large angle (see *E. Jb.*, 1891 and 1893; M. von Rohr's *Geschichte*, and O. Lummer, *Photographic Optics*, for further details). They were issued by Messrs Zeiss and their licencees (in England, Messrs Ross), in 1890, in two different types. The more rapid had five lenses (fig. 31), two of ordinary glasses in the front normal achromat, and three in the back abnormal achromat, two crowns of very high refractive power, with a negative flint of very low refractive power between them.

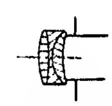

FIG. 33.—Anastigmat. Series VI.

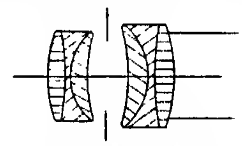

FIG. 34.—Satz Anastigmat. Series VI*a*.

The fifth lens assisted in removing spherical aberrations of higher orders with large apertures. The second type, series III*a*, *f*/9, 1899 (fig. 32), had only two lenses, the functions of which were as above. These combinations could not be used separately as single lenses. They are now issued as "Protars," series II*a*., *f*/8; III*a*., *f*/9; V., *f*/18. In 1891 Dr Rudolph devoted himself to perfecting the single landscape lens, and constructed on the same principle a single combination of three lenses, the central one having a refractive index between the indices of the two others, and one of its cemented surfaces diverging, while the other was converging. At *f*/14·5 this lens gave an anastigmatically flat image with freedom from spherical aberration on or off the axis. It was, however, not brought out till 1893, as a convertible lens or "Satz-Anastigmat," series VI., *f*/14·5, and VI*a*., *f*/7·7 (figs. 33 and 34). In the meantime Dr E. von Höegh (C. B. Goerz) and Dr A. Steinheil had also been working at the problem and had independently calculated lenses similar to Rudolph's, but, whereas he had devoted himself to perfecting the single lens, they sought more perfect correction by combining two single anastigmatic lenses to form a doublet. Dr Rudolph had had the same idea, but Messrs Goerz secured the priority of patent in 1892, and in 1893 brought out their "Double Anastigmat," now known as

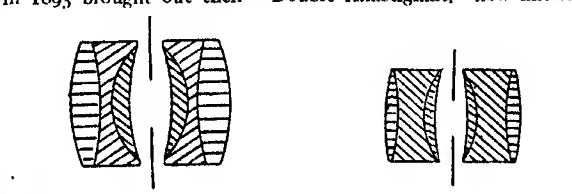

FIG. 35.
Ross-Goerz "Dagor." Series III. Ross-Goerz. Series IV.

"Dagor." It was the first symmetrical anastigmat which combined freedom from astigmatism with flatness of field and great covering power at the large aperture of *f*/7·7 (fig. 35). Both these types of Zeiss's "Protars" and Goerz's "Dagor" anastigmats have since

camera, the front of it formed of light-proof cloth and the back by the curved flexible carriers. The lens is fitted on a vertical axis, so that the nodal point of emergence remains motionless, and is revolved round it by means of a handle worked by hand and carrying a view meter. The illumination of the image is regulated by an adjustable vertical slit in a tube attached to the lens inside the box, and by altering the rate at which the lens is revolved. The pictures taken embrace less than 180°. The apparatus folds together and is quite portable; it is fully described in Moessard's *Le Cylindrographe* (Paris, 1889). The "Al-Vista" (1901) and the "Panoram Kodak" (1900) are on the same principle, but arranged as roll-holder hand cameras, in two sizes, carrying film for several exposures, 7 in. × 2¼ in. or 4 in. × 12 in. They work instantaneously, and by means of a clock-spring the lens rotates rapidly over a half-circle when released. The angle of view is about 120° (figs. 11 and 12). The views taken with this kind of camera are sometimes disappointing, on account of the development of cylindrical perspective on a plane surface causing apparent distortion. This distortion is avoided in Carl Zeiss's "Palmos Panoram" camera for plates 6¾ in. × 3¼ in., fitted with "Tessar" lens and focal plane shutter, and other similar cameras which can be used for stereoscopic or single pictures. Other more elaborate instruments driven by clockwork have been made for making a complete tour of the horizon. Among them C. Damoizeau's "Cyclographe," which can be used with lenses of different foci and takes the pictures on a roll-film, which is unrolled as the instrument revolves on its axis, the lens also rotating on its nodal point of emergence; and thus the image always remains sharp (*Bull. Soc. Franc. d. Phot.*, 1891, p. 183,). Commandant A. Daubresse has improved on Moëssard's apparatus, by placing the lens vertically between two right-angled prisms, the upper of which receives the image and projects it through the lens on to the lower prism, from which, by rotation of the system on the vertical axis, it is projected on to a cylindrical film through an angle of 360° (ibid. 1906, p. 430; *E. Jb.*, 1907, p. 91). The "Periphote" and Ernemann's "Rundblick" camera are improved forms (*E. Jb.*, 1908, p. 322).

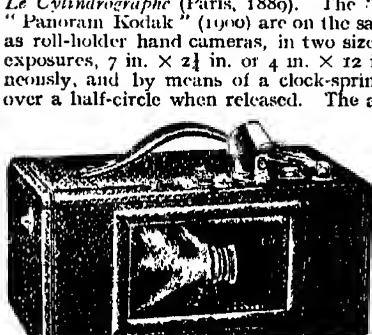

FIG. 12.—"Al-Vista" Panoramic Camera, closed.

Many early forms of panoramic cameras are described in *B. J. A.*, 1892, p. 517. Colonel R. W. Stewart's "Panoram" (1893), A. Chevalier's "Photographic Plane Table," J. Bridges Lee's "Photo-Theodolite" (1894), and similar cameras fitted with telescopes, levels and divided circles, are instruments of precision suitable for photographic surveying. Improved instruments for topographical surveying with stereo-photographic apparatus, on the principle worked out by Dr C. Pulfrich, of Messrs Zeiss & Co., in his stereo-comparator (1903), are being practically developed, and much information regarding them will be found in papers by E. Dolezal and others in J. M. Eder's *Jahrbucher*, 1903 to 1908; also a papor by Lieut. F. V. Thompson in *Geographical Journal*, 1908, xxxi. 534.

Cameras for Three-Colour Photography.—Many forms of camera have been constructed for making the three negatives required for trichromatic photography. They fall into two types: (1) those with a repeating back fitted with three colour-screens or filters—red, green and violet—through which the colour impressions are made successively with one lens upon a single colour-sensitive plate, as in the Sanger-Shepherd system. The colour-screens are placed immediately in front of the sensitive plate in the repeating back, which is moved on for each exposure. In a more recent form, by the same maker, the three images are taken on the sensitive plate with one exposure. The camera is divided into three compartments, and fitted with a special diaphragm which can be regulated for the varying sensitiveness of different batches of plates. The central image is impressed directly on the plate; the other two by reflection from prisms arranged so as to equalize the sizes of the three images on the sensitive plates, the light rays passing in each case through a suitable colour-filter—red, green and blue-violet—somewhat on the principle of F. E. Ives's camera of 1900 (fig. 13). It is convenient and successful in working. (2) Cameras made on the reflecting principle of L. Ducos du Hauron (1876), elaborated by F. E. Ives (1894) in his photochromoscope, in which three images are taken through three colour-screens on separate plates with one lens, the respective exposures being regulated by reflection of the light coming from the lens by plane mirrors on to the sensitive plates, and its filtration through the colour-screens in front of them. Many variations of this method have been proposed, in which reflecting prisms replace the mirrors. The different systems have been discussed by W. Gamble (*Ph. Journ.* 1905, xlv. 150), the latter also by E. T. Butler (ibid. p. 199). Sir W. de W. Abney has described three-colour cameras for landscape work in *Ph. Journ.* 1904, xliv. 81, and 1908, xlviii. 331.

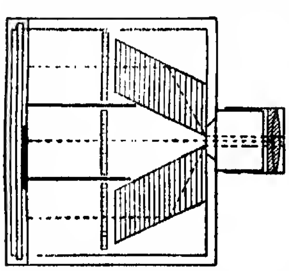

FIG. 13.—Diagram of Camera for Three-colour Photography.

Enlarging Cameras.—These cameras vary in form, according to the nature of the illumination, but ordinarily consist of a double or triple extension bellows camera, with a holder for the negative or transparency at one end, and for the sensitive plate or paper at the other, the lens being placed on a fixed partition between the two. Some recent forms of "daylight enlargers" can be used as an ordinary camera. Other cheaper ones are on the fixed focus principle. Enlargers for use with artificial light are made like a magic lantern, with a condenser, projecting an enlarged image on to a sensitive plate or paper fixed on an easel or screen. A simple arrangement for daylight enlarging is to fix a suitable camera on to a larger one by a sliding front, and mount the two on a studio stand tilted so that the image may be illuminated by the open sky.

Cinematographs.—Many special cameras and lenses have been introduced for taking on a long flexible sensitive film an extended series of small photographs of the successive phases of movements, and again projecting them on a screen so as to reproduce the scene, with an illusion of motion, in what are known as "living pictures," biographs, &c. As each photograph requires a certain minimum time for exposure and must be kept in true position in sequence with the rest, some means of regulating the intermittent exposures and keeping the film in position have to be adopted; and there are many different ways of doing it, either by a continuous or intermittent motion and exposure of the film while it is being unwound from one roller on to another. The films used are similar to the ordinary celluloid films, but in narrow bands from 1⅜ in. to 2⅜ in. in width, the length varying with the number of exposures required, at the the rate of 16 to 20 per second. They are perforated on both sides, so that they may run true and have the necessary intermittent motion, the perforations fitting on to studs on a sprocket wheel in connexion with the driving wheel and crank handle. Special lenses of short focus, from 1 in. to 3 in., with good covering power and large apertures $f/4$ to $f/2$, are required both for photographing and projecting; several such are noted below. Absolute rigidity in the camera is essential. Special stands are made for the purpose, but if a tripod stand is used it should be well braced. Special apparatus is required for developing and fixing the exposed films. They are wound on large rollers supported over troughs containing the necessary solutions (see CINEMATOGRAPH). The mechanical arrangements are treated in H. V. Hopwood, *Living Pictures* (1899); F. P. Liesegang, *Handbuch der praktischen Kinematographie* (1907); K. W. Wolf-Czapek, *Die Kinematographie* (1908); G. Lindsay Johnson, *Photographic Optics* (1909); Eder's *Jahrbucher*.

A method of cinematography in colour was introduced by G. A. Smith and C. Urban in 1908, the main features of it being the use of a film sensitive to *all* colour waves to the furthest red; superimposing the colour records by persistence of vision; the use of two-colour records instead of three, in order to reduce the interval between the successive presentations; adaptation to existing cinematograph machinery and films. These conditions are fulfilled by the use, in place of the ordinary revolving sector shutter in front of the lens passing intermittent white light, of a special, more rapidly revolving shutter divided into four sectors, one fitted with orange-red glass, another with bluish-green glass and two intermediate opaque sectors, so that at every revolution of the shutter an exposure is made through the red and green glasses alternately. The former passes white and yellow, and then orange, scarlet to deepest red; whilst the latter also passes white and yellow, green, blue-green, blue, all in proportion according to the red and green sensitiveness of the specially sensitized panchromatic emulsion on the film. The same shutter and colour screens are used for projection, some supplementary blue rays being added. The results are satisfactory and the method promises to be of great practical value (see *Journ. Roy. Soc. Arts*, 1908, 57, No. 2926).

Special cameras are made for various branches of scientific research in photo-micrography, photo-spectroscopy, astronomical photography, &c.

Tripod Stands.—Field cameras are usually supported on wooden tripod stands, folding in two or more sections, the head being separate or fixed in the base-board of the camera. The legs should be capable of extension to about 5 ft. and adjustable in length for use on uneven ground. A tripod stand may be light, but must be firm and rigid when set up. To prevent slipping, shoes of india-rubber or cork may be fitted to the points of the legs, and in some cases it may be desirable to strengthen the tripod by a folding adjustable brace. W. Butler's "Swincam" camera stand is made to enable the camera to be securely fixed in awkward positions, and has many valuable special features, great extension, swivel points to the feet, &c. For hand cameras the very light, portable metal folding and walking-stick stands are convenient.

consists of two unsymmetrical combinations, each formed of two single lenses of very transparent glass, dense baryta crown and light flint, separated by positive and negative air-spaces (fig. 44). The separate halves cannot be used as single lenses, neither being fully corrected for colour. It is well adapted for portraiture, groups or landscapes, especially for rapid hand-camera work, on account of its covering power, with freedom from astigmatism and sharp definition with large relative aperture.

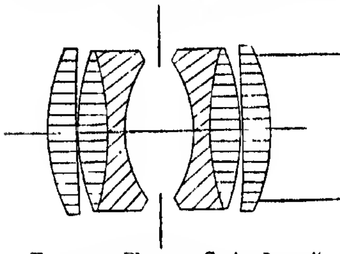

FIG. 43.—Planar. Series I*a*. *f*/4.

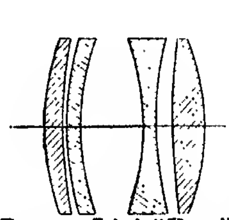

FIG. 44.—Zeiss's "Unar."

In 1898 Messrs Goerz patented their "Double Anastigmat Celor," series I*b*., *f*/4·5 to *f*/5·5. It is a symmetrical doublet, each element consisting of two thin single lenses: a positive of high and a negative of low refractive index, separated by an air-space (fig. 45). It is derived from the triple anastigmats by decreasing the refractive power of the central convex meniscus to the refractive power of air, so that it becomes a convex air-space between a double convex and a double concave lens. Less deeply curved surfaces can be given to the lenses, and the doublet gives anastigmatic flatness of field over an angle of 62° to 66°, equal to the best anastigmats with a still larger aperture. Series I*c*., *f*/6·3, is similar and recommended for hand cameras, the aperture being smaller. Goerz's "Hypergon," (1900) *f*/22, angle 135°, is a

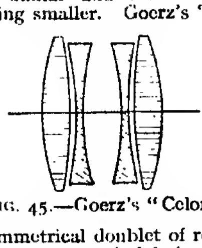

FIG. 45.—Goerz's "Celor."

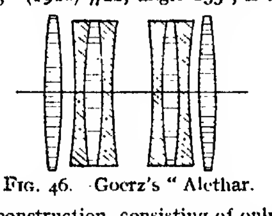

FIG. 46. Goerz's "Alethar."

symmetrical doublet of remarkable construction, consisting of only two single semi-globular, very thin lenses, with diaphragm at the centre of curvature between them. Astigmatism and curvature have been eliminated, and definition is good over the above wide angle with no distortion. Chromatic aberration is uncorrected, but compensated for by using a small stop. A star mask is fitted in front of the lens to allow for falling off of illumination towards the margin (*E. Jb.*, 1901, p. 103). The "Syntor" (1903), Series I*d*., *f*/6·8, angle 64° to 70°, is on the same principle as the "Celor," but cheaper, for use in hand cameras or telephoto combinations. The "Alethar," series V. (1903), *f*/11, is a lens with diminished secondary spectrum, for three-colour reproductions, half-tone process work, and general purposes. It is a symmetrical doublet, each element consisting of a negative and positive separated by an air-space (fig. 46). The negative is composed of three cemented lenses, which correct the spherical and chromatic aberrations more fully than hitherto possible, so that all the colours of the spectrum are focused in the same invariable plane. It gives great crispness of definition at full aperture (W. Zschokke, *E. Jb.*, 1904, p. 165). Goerz's "Pantar," *f*/6·3 (1904), is a convertible 4-lens anastigmat, and an improvement on the "Dagor," in that the single elements are completely corrected for coma, and thus form efficient long-focus lenses for landscape, &c., at an aperture of *f*/12·5, while the doublets formed by various combinations of the single elements are universal objectives working from *f*/6·3 to *f*/7·7. The single elements are similar to those of the "Dagor," but have an additional negative

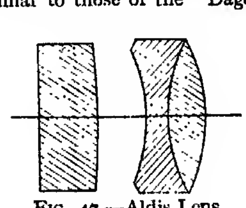

FIG. 47.—Aldis Lens. Series II.

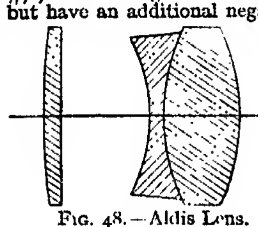

FIG. 48.—Aldis Lens. Series III.

lens at the back, so that the outer two of the three cemented surfaces have a collective and the inner one a dispersive action, by which coma is eliminated (*E. Jb.*, 1905, p. 55).

In 1902 H. L. Aldis issued the "Aldis Lens," *f*/6, a doublet composed of a cemented meniscus in front and a single double-convex back lens. It is a long-focus objective with short back focus, and is made in two forms, series II., *f*/6 (fig. 47), and series III. (1903), *f*/7·7 (fig. 48). In the latter the back element is very thin, and the front combination of infinite focal length. By discarding the symmetrical form simplicity is secured, while open or reflecting surfaces are avoided. Special attention has been paid to perfect correction of spherical aberration in the centre of the field. It is lighter, smaller and cheaper than series II. The "Duo" lens of the same maker (1907) is intended to replace the front lens and double the focus, but with less rapidity and without any loss of quality. The "Trio" (1908) is similar, but only increases the focus one and a half times and is thus more suitable for cameras of short extension The Aldis "Oxys" anastigmat, Series II. (1908), *f*/5·65, angle 85°, is an improved form. Being an unsymmetrical cemented doublet it is free from the defects incidental to air-spaces and is constructed to give more perfect correction for flatness of field with large aperture and wide angle.

It is generally stated that it is impossible to make a spherically, chromatically and anastigmatically corrected photographic objective with the old optical glasses. K. Martin, of Messrs Busch of Rathenow, has, however, shown (*E. Jb.*, 1902, p. 68) that it is quite possible to do so with a system of separated lenses, and that it is immaterial whether the index of the flint or the crown is the higher. An anastigmat on this principle was issued by Messrs Busch in 1902, as the "Omnar," series III., *f*/7·7 (fig. 49). Series II., *f*/5·5, angle 75°, and I., *f*/4·5, have since been issued. It is a symmetrical

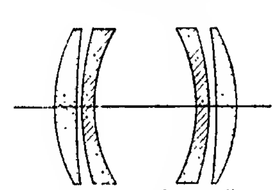

FIG. 49. "Omnar," Series III.

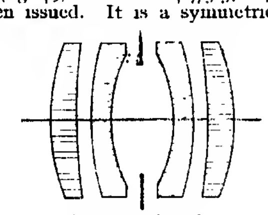

FIG. 50. Ross's "Homocentric."

doublet, each element consisting of a negative flint meniscus of higher refraction, and a positive crown of lower refraction with an air-space between them in the form of a negative lens. The back element can be used alone. The "Lumar" series, by G. Rodenstock, is similar. In 1902 Messrs Ross brought out the "Homocentric," a symmetrical doublet, each element consisting of a negative and positive meniscus separated by an air-space (fig. 50). It is constructed so that all rays of light emanating from any one point of the object are converged again into one point in the image. It is also quite free from spherical zones, is not altered in focus with different diaphragms, and thus has exquisite defining power. The colour correction is so perfect that the different coloured images are identical in size and position, thus rendering it specially suitable for three-colour and process work. The back lens can be used alone, with diaphragms, as a single lens of about double the focus of the doublet. It is made in several series: II., *f*/5·6, and III., *f*/6·3, for rapid and instantaneous work; V., *f*/8, for ordinary purposes; VI., *f*/8, for process work and three-colour reproduction. A later series, IV. (1907), "Compound Homocentric," *f*/6·8, differs from the others in being a symmetrical doublet composed of two triple cemented elements, very close together and separated by a diaphragm. It is

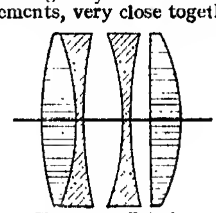

FIG. 51.—Zeiss's "Tessar."

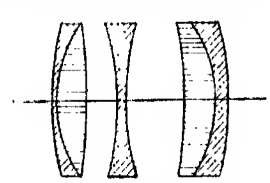

FIG. 52.—Voigtländer's "Heliar."

specially suitable for outdoor work, also for copying and enlarging, having good covering power. Zeiss's "Tessar" (1902) is a rapid unsymmetrical doublet, formed of two separated uncemented positive and negative lenses in the front element and a cemented meniscus at the back (fig. 51). The two halves cannot be used separately. The glasses used are very transparent, permanent and lessen the secondary spectrum. Three series are made by Messrs Ross, I*c*., *f*/3·5 for cinematographic work and portraiture, and *f*/4·5 for hand-camera work and portraiture; II*b*., *f*/6·3 for general purposes, and VIII., the "Apochromatic Tessar," specially corrected for three-colour work and reproduction. They all give fine definition over a large flat field, free from any zonal aberration. The *f*/3·5 portrait lenses, with double the field and covering power of the Petzval lens, are anastigmatic and free from distortion. Messrs Voigtländer's "Heliar" (1902), *f*/4·5, angle 50°, calculated by Dr H. Harting, is an objective of large aperture, suitable for portraits and very rapid instantaneous work, being well corrected for astigmatism, coma and curvature of field, with freedom from flare. It is a triplet consisting

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

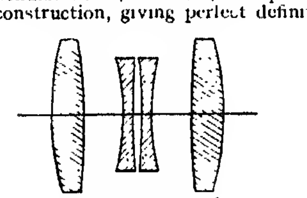

FIG. 53.—Beck-Steinheil "Unofocal."

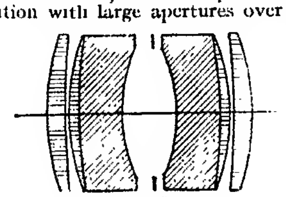

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°–65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

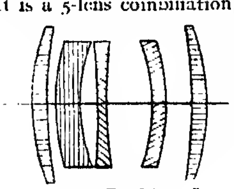

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Borie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Telediopticus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

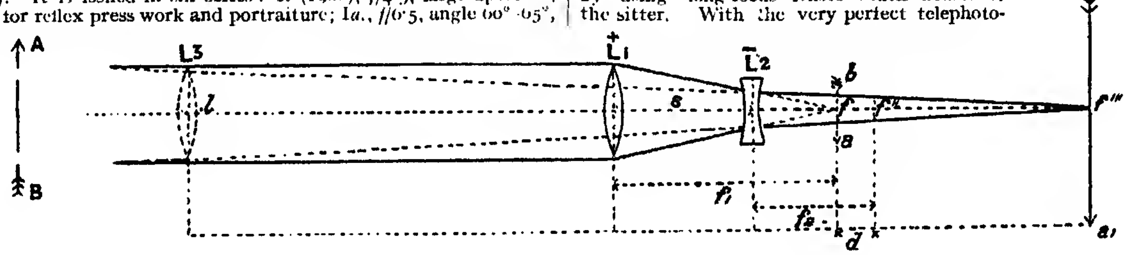

FIG. 56.

with those of ordinary intensity the exposures are not unduly prolonged, and good definition can be obtained over an extended field.

The optical principle on which these combinations are based is very simple, and will be understood from fig. 56. It depends mainly on the fact that in order that a *real* image may be thrown on the screen of an object AB, the rays proceeding from it, which pass through the positive system L_1, must come to a focus at a point f within the secondary focus f'' of the negative system L_2. Falling within this limit, they will be intercepted by L_2 and made less convergent, so that instead of coming to a focus at f, they will continue to converge till they reach the screen at f'', and will there form a proportionally larger image $a'b'$ of AB than the image ab given by the positive lens alone at f; just as stated in Kepler's problem. Moreover, this image $a'b'$ will be of the same size as if it had been produced directly by a positive lens L_3 with a focal length equal to tf'', and this distance is the equivalent focal length of the entire system. It can be found from the formula $F = f_1f_2/d$, where f_1 and f_2, are the focal lengths of L_1 and L_2 respectively, and $d = f_1 + f_2 - s$, s being the distance between the lenses. In many instruments of the kind a scale showing the value of d is engraved on the mount. If the rays from AB come to a focus in front of L_2, on it, or beyond f'', no real image can be projected on the screen. There is therefore a certain limit, which is greater in proportion to the length of focus of the negative system, within which the focus of the positive system L_1 may fall and produce a series of well-defined images on the screen, which can be varied in size by altering the amount of separation of the two systems of lenses within the above limit, and the distance of the screen from L_2. Every change in the position of the screen will involve a corresponding adjustment of the lenses. The greater the extension of the camera and the closer the lenses, the greater the size of the image, and vice versa. The camera extension for a given magnification can be found by multiplying the focal length of the negative system by the number of magnifications, less one. The magnification produced by a given camera extension is found by dividing the latter by the focal length of the negative system, and adding one.

In its usual form (fig. 57) the telephotographic combination consists of a quick-acting portrait lens, or an anastigmatic doublet of

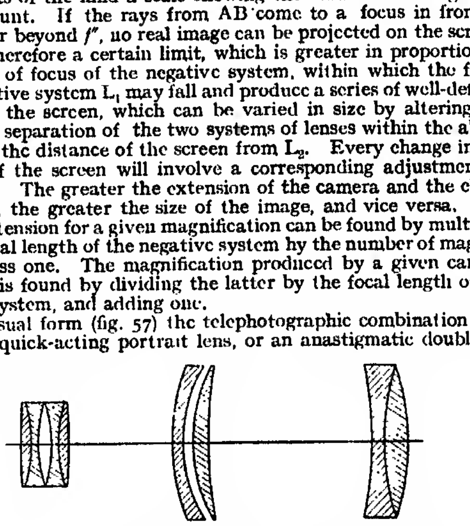

FIG. 57.—T. R. Dallmeyer's Compound Telephotographic Lens.

large aperture and relative intensity of suitable focal length, fitted at one end of a tube, in which slides a smaller tube carrying a properly corrected negative system, which may vary in focus, but must be of shorter focus than the positive (usually about half); the shorter the focus the greater the magnifying power for a given extension of camera. The amount of separation of the lenses is limited on the one hand by the position of the focus of the positive system, and on the other by the focus of the negative system, as explained above, and can be adjusted within these limits by a rack and pinion. The tubes are adjusted so that when closed up the two foci may coincide, or nearly so, and $d = 0$, or its minimum value; and when opened to their fullest extent the focus of the positive may fall upon the negative system, or so that d may not exceed the focal length of the negative system. Within these limits the focal length of the combination will be positive, and a real image formed on the screen. Several forms of them have been brought out by various makes, some, as Zeiss's, with a special positive lens, others for use with anastigmats and other lenses of large apertures. The negative lenses are also made of various powers.

Messrs Dallmeyer's "Adon" (1902) is a telephotographic lens, for use with hand cameras, composed of two achromatic combinations adjusted for parallel rays, a front positive lens $4\frac{1}{2}$ in. focal length, and a back negative lens of $2\frac{1}{4}$ in. focus. These are mounted to permit of great variation in the separation, so that when the "Adon" is fixed on the *front* of a suitable lens, near or distant objects may be taken on an enlarged scale without altering the focus of the camera, or the enlargement can be varied with further extension of the camera. Used alone it is a complete telephoto lens of moderate magnifying power, and will cover plates 15 in. × 12 in. In 1903 a special form, the "Junior Adon," was made in three kinds for use with kodaks and similar folding hand cameras, single and double extension, giving a fixed degree of magnification without loss of rapidity, while focusing can be effected by scale. It is intended to replace the front lens of an R.R. or anastigmatic lens and cannot be used independently. Messrs Busch's "Bis-Telar" $f/9$ (1905), is another compact fixed focus telephoto lens, specially for use with hand cameras. It is a complete lens in itself, requiring no attachments and can be fitted to a central shutter. It is made in three sizes magnifying from two to three times. An improved form of this lens (1908), working at the large aperture of $f/7$, is similar to an old form of "Dialytic" lens worked out by J. Petzval, having a positive front and negative back meniscus, with their concave surfaces facing inwards (fig. 58). As in the old "Orthoscopic" and lenses of that type there is some outward distortion, but it is very slight. These lenses are made in five sizes with foci from 8 to 22 in., requiring camera extensions from $4\frac{1}{2}$ in. to $11\frac{1}{2}$ in. They magnify about twice. According to K. Martin, a telephoto-combination of the Bis-Telar type can be used in a reversed position as a projecting lens for the lantern, with the advantage of increasing the illumination from a given source of light (*E. Jb.* 1908, p. 46).

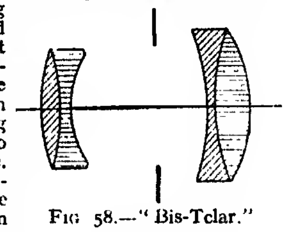

FIG. 58.—"Bis-Telar."

Captain Owen Wheeler proposed in 1907 a high-power telephoto arrangement, made by Messrs Staley, in which the negative attachment consists of three negative lenses, any single one of which can be used separately, giving magnifications of about 6, 9, and 13 diameters with a camera extension of 14 in. By combining the three a magnification of 30 diameters is attainable with the same short extension, which is a great advantage in many ways. In 1908 Messrs Zeiss issued their "Special Tele-objectives" in two sizes working at $f/10$, the larger with an aperture of 3·14 in. and 32 in. focal length fitted in a special "tele-camera" for plates 9 × 12 cm. with a monocular field-glass magnifying four times as finder. The smaller one, with 18 in. focus, is adapted for hand cameras with 6 in. bellows extension. They consist of specially corrected positive and negative combination with a definite focal length and requiring a definite camera extension, and are specially suitable for balloon photography, instantaneous portraiture, &c. The theory, construction and use of telephoto lenses has been fully described by T. R. Dallmeyer in his *Telephotography*.

7. *Anachromatic Lenses.*—For large portraiture a certain amount of softness and diffusion of the image has long been recognized by artists as desirable, and in 1895 the "Dallmeyer-Bergheim Lens" was constructed with this special object. It is composed of a single uncorrected positive meniscus front lens, with a diaphragm in front of it, and an uncorrected negative meniscus back lens, and in the larger sizes it has great range of focal length on the telephotographic principle. The spherical and chromatic aberration produced by the uncorrected single lenses gives the diffusion of focus which produces the peculiarly soft and delicate effect aimed at. It is most useful for large heads and life-size studies, the great depth of focus conducing to uniformity of definition. There is no distortion, and by stopping down to about one-third perfect definition can be obtained. It works with great brilliancy, both elements being single glasses. It was the first of the anachromatic portrait lenses. Since 1903 Messrs C. Puyo and L. de Pulligny have been experimenting with various combinations of uncorrected lenses for producing the same effect in portrait and landscape photography by the diffusion of focus produced by chromatic aberration, and suitable lenses of this kind have recently been brought out in Paris as *Les Objectifs d'artiste*. In their construction the principal points to be considered are *spherical aberration*, to be minimized in the form and arrangement of the lenses selected; *distortion*, corrected by using a symmetrical system; *astigmatism*, avoided by using combinations of low power. The lenses used by Puyo have been : (1) a plano-convex crown with convex side in front at $f/8$ or $f/9$, or even $f/5$ for heads; (2) a simple thin concavo-convex meniscus, with concave side in front, is better and suitable for full lengths at $f/10$; (3) a symmetrical system formed of two similar crown menisci, concave sides inwards, is generally useful when worked at $f/10$, or even $f/5$. Arrangements are made in mounting these lenses for automatically making the necessary correction for colour. Another form is the "Adjustable Landscape Lens," formed of an anterior plano-convex crown, 3 cm. diameter, and a posterior plano-concave crown, each of 10 cm. focus, and the same radii of curvature. In contact they have an infinite focus, but when slightly separated any focus can be obtained up to about 10 cm. In such a telephotographic system, properly stopped down, anastigmatism, flatness of field, and rectilinearity are secured over a fairly large field. These lenses are fully described in *Les Objectifs d'artiste*, by L. de Pulligny and C. Puyo (Paris, 1906), and various forms, portrait and landscape, have been made by Messrs Hermagis, Turillon & Morin (see Fabre, *T. E. P. Suppl. D.* 101).

Diaphragm Apertures.—In order to regulate the intensity of the illumination by the lens, to enlarge its field, and, in the case of the older forms of objectives, to extend the area of good marginal definition, diaphragms are used, usually with circular apertures. They are made in different ways : (1) as single metal plates, fitting into a slot in the lens tube (Waterhouse diaphragms); (2) Rotatory : a single plate revolving on a central axis and pierced with apertures cut to fit centrically in the opening of the lens; (3) Iris : a form of diaphragm now very generally used, and very convenient, because it can be easily adjusted as required for intermediate apertures. As a rule they are placed at the optical centre between the elements of a compound lens or in front of a single one.

In order to provide a uniform system of diaphragm apertures.

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

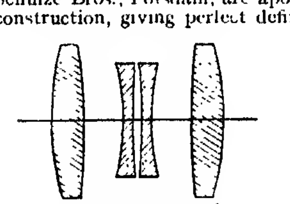

FIG. 53.—Beck-Steinheil "Unofocal."

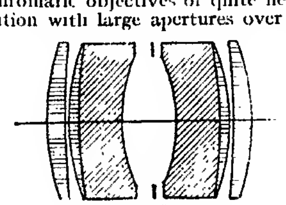

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

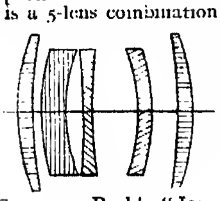

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1860 by MM. Porro and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

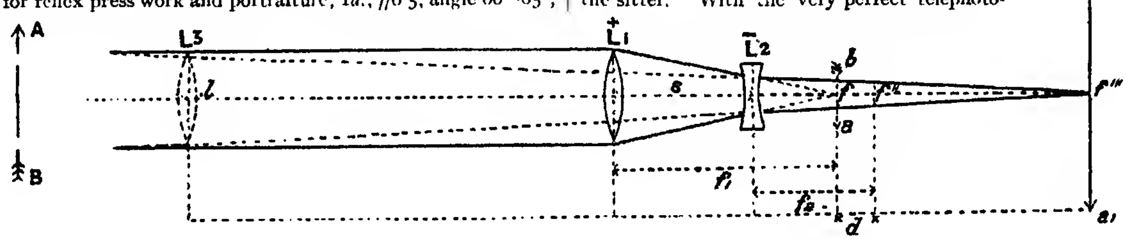

FIG. 56.

what is more important, how far they can be depended on for regularity. There are many simple ways in which the actual time of exposure from opening to closing can be ascertained sufficiently closely for practical purposes. They depend upon the measurement of the trace left on a sensitive plate by the passage of a brightly illuminated object revolving at a known speed or falling vertically through a known distance, when photographed with different speeds of the shutter against a dark background. These, and the more elaborate methods for obtaining more accurate determinations of the shutter-exposure periods and of the corresponding effective exposures —*i.e.* showing the actual effect of the shutter through its different phases from opening to closing—have been described by Sir William Abney in the work already mentioned, by A. Londe in *La Photographie moderne* and *La Photographie instantanée*. An apparatus for testing shutters at the National Physical Laboratory was described by J. de Graaf Hunter in the *Optician*, 1906.

1. *Flap Shutters.*—The simple flap shutters consisting of a hinged flap opening upwards in front of the lens, though favourites in early days for landscape work, and still useful for intermittent exposures or as sky-shades for securing cloud effects or increasing foreground exposures, have been almost superseded by quicker and more compact forms. They are used with single and double flaps for portraiture and studio work, for which purpose they are made to act noiselessly and not attract the attention of the sitters. Guerry's (figs. 59 and 60) is a good example of the type. W. Watson's "Silent" shutter is hemispherical in form and collapsible, the two wings opening out and folding together, when actuated by a special "Antinous" release, and R. & J. Beck's is another form, a single lifting flap with pneumatic release.

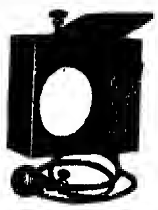

FIG. 59.—Guerry's Single-flap Shutter.

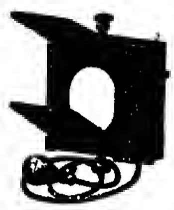

FIG. 60.—Guerry's Double-flap Shutter.

2. *Drop Shutters.*—The old simple drop shutter, in which a plate having an opening in it falls in front of the lens aperture, has been superseded by the more compact and quicker-working roller-blind shutters, which act on much the same principle. It had a theoretical interest in connexion with the effect of different forms of aperture—circular, square, or elongated—used with shutters of the lateral type, but it is now generally recognized that a more or less extended rectangular opening, of at least the full width of the lens aperture, is best for securing the even admission of light from all parts of the image with shutters of the rectilinear lateral type, to which this and similar shutters, in which a single opening passes across the lens aperture, belong. In Busch's "sky shade" shutter (1907), fitting on the front of the lens a single leaf moves vertically upwards and descends again, giving less exposure to the sky.

3. *Combined Drop and Flap Shutters.*—In early dry-plate days several forms of this kind of shutter were brought out, under the names of Phoenix, Phantom, &c., but are now little used. In these shutters, in addition to the drop slide, there was also a lifting flap, which on release opened from below, and, having fully uncovered the aperture, released the drop slide, which fell and closed the shutter. They were useful and effective in the smaller sizes, but heavy and cumbrous in the larger. Speed could only be estimated very roughly by the use of india-rubber bands for giving tension.

4. *Rotary Shutters.*—These are of the lateral type, and consist of a circular metal disk revolving on an axis eccentric to the axis of the lens, and furnished with a radial sector-shaped opening, which passes laterally in front of the lens aperture when the tension of a spring is released (fig. 61). They are used in various patterns in cheap hand cameras, usually in front of the objective, though they may be placed behind it or between the component lenses. So long as the opening is at least equal to the size of the lens aperture, the illumination is sufficiently even, but the openings are usually elongated so as to give a longer period of full opening. Working by a spring they are more portable and convenient than drop shutters. Beck's "Celverex" between-lens shutter (1906) is of this type, the disk being revolved by a spring and the variations of exposure obtained by altering the size of the opening passing over the lens aperture, and not the tension of the spring. It is speeded for exposures of $\frac{1}{10}$, $\frac{1}{20}$, $\frac{1}{40}$, $\frac{1}{80}$ sec.; also "bulb" and "time." It is fairly accurate and consistent in action, but loses efficiency at the highest speeds by the diminution of the opening.

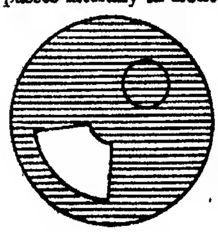

FIG. 61.—Rotary Shutter.

5. *Roller-Blind Shutters.*—For general use the well-known roller-blind shutter of the single lateral type, as made by Thornton-Pickard and others, is undoubtedly one of the most popular and efficient. It possesses most of the qualities laid down as essential to a good shutter, gives good illumination, appears to be fairly regular in its action, and can be used for time or instantaneous exposures. It consists of a light mahogany or aluminium box, arranged so that it can be fitted in front of or behind the objective. It is made in different sizes, and each size can be adjusted to smaller objectives (fig. 62). It is also made with a disappearing cord, and in an improved pattern, the "Royal," all the fittings are inside the box. By pulling the cord an opaque black curtain with an elongated rectangular aperture is unrolled from the lower roller on to the upper one, and held by a coiled spring on the lower roller (fig. 63). Pressure on a pneumatic bulb inflates a second smaller bulb, raising a lever which releases the spring, and thus brings the blind down with a rapidity which can be adjusted by turning a handle actuating the spring, the corresponding speed being shown on an indicator. For time exposures, pressure on the bulb opens the shutter, and another pressure closes it, but an arrangement is now made by which time exposures of $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, 1, 2, 3 seconds can be given automatically, the pressure of the bulb opening the shutter, which closes of itself at the expiration of the exposure required. The theory of shutters of this type has been very fully discussed by Coventry (*op. cit.* p. 50), who shows that for any given tension of the spring the actual exposure decreases as the size of the lens aperture diminishes, while the effective exposure remains constant for all apertures. This is peculiar to the lateral shutter. He also shows that with plates of very different rapidities, though the exposure may be the same, the actual exposure effective is less with the rapid plate and a small stop than with the slow plate and a large stop; consequently the blur due to the movement of the object would be proportionately less on the rapid plate than on the slow one. Also that for any given lens the smaller the shutter the more rapid the exposure can be made, though with the same lens a larger shutter is capable of giving a more efficient though less rapid exposure. It is better, therefore, for moderate exposures, to have a larger shutter than the size of the lens requires. Sir William Abney has given diagrams of the action of a shutter of this kind in his book referred to; they show clearly that the centre of the plate gets more exposure than the margins; but practically this is not very noticeable, and the action is very regular.

6. *Focal Plane Shutters.*—These are also roller-blind shutters with mechanism similar to the foregoing, but arranged so that the slit in the curtain may move rapidly close in front of the sensitive plate, exposing different portions of it in turn, the intensity of the exposure being regulated by the width of the slit, whether adjustable or not, and the rapidity with which it is moved by the unwinding of a spring. The advantages of these shutters are now being fully appreciated, the principal being that they are quite independent of the lens, so that one shutter will serve for different lenses, and any suitable lens may be used at its full intensity, without the loss of efficiency inherent in the ordinary forms of lens-shutters. They thus add effectively, if not actually, to the speed of a slow lens, or if a lens be stopped down there is less loss of efficiency, with a gain in increased depth and definition. They are particularly well adapted for the very short exposures required in photographing near and quickly moving objects, racing horses, divers, &c., and many reflex and other hand cameras are fitted with them. They are constructed in different forms, either for short exposures with high speeds alone, or for short and prolonged exposures; with a single slit of fixed or variable width moved at regulated speeds, or with a series of slits or openings varying in width, their speeds being adjusted by the

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

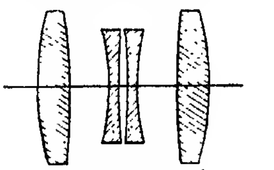

FIG. 53.—Beck-Steinheil "Unofocal."

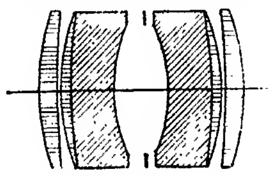

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f) = 0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

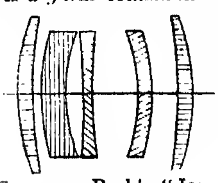

FIG. 55.—Beck's "Isostigmar."

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Bonie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

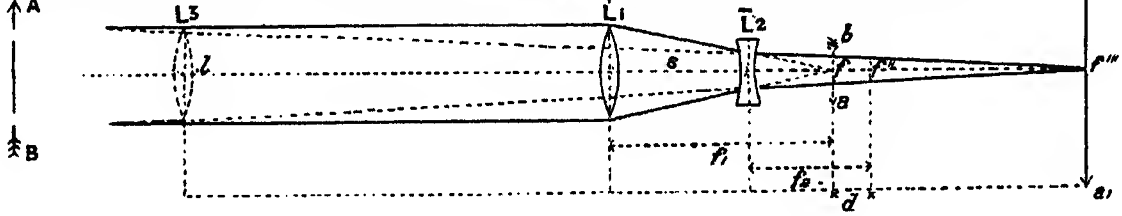

FIG. 56.

denoting the sensitiveness of their different brands, and is more or less the basis on which the plate-speeds for the modern English dry-plate actinometers and exposure meters are calculated. Several systems of photometry and measurement of the speeds of dry plates have been discussed at the meetings of the *Congrès International de Photographie*, in 1889, 1891, 1900 and 1905, but no definite standard has been finally adopted. In Germany the use of J. Scheiner's sensitometer has been adopted, and appears to be extending. It is based on a system of photographing the graduated tints given by rotating sectors. A full account of the instrument, and of a system of sensitometry based on its use, is given by J. M. Eder in the *Photographische Correspondenz* (1898), p. 469, and (1900) p. 244. In 1901 Chapman Jones brought out a convenient plate-tester on the same principle as the Warnerke sensitometer, but extended by the addition of a colour sensitometer, which is useful for the comparison of orthochromatic dry plates, colour screens, light filters, &c. It consists of a screen plate, $4\frac{1}{4} \times 3\frac{1}{4}$ in., containing a series of twenty-five tints of graduated densities; a series of coloured squares, blue, green, yellow and red, and a strip of neutral grey, all five being of approximately equal luminosity; a series of four squares of special pure colours, each representing a definite portion of the spectrum; also a space of line design, over which is superposed a half-tone negative. To use the instrument, a quarter-plate of the brand to be tested is exposed behind the screen for a few seconds to the light of a standard candle placed at the distance of a foot, developed, fixed and washed. An examination of the plate will show the sensitiveness, range of gradation, possible range of exposure, sensitiveness to colour, size of grain, amount of halation, and the most suitable light for development. It can be used for many other tests, and enables any brand of plates to be readily tested by the user and compared with any standard he may find convenient. In making these and similar tests, a standard developer should be allowed to act for a fixed period and at a uniform temperature (*Ph. Journ.*, 1901, 25, p. 240).

The next important factor is the actinic power of the light. It depends normally on the height of the sun for the latitude of the place at the time when the photograph is taken, and exposures in bright sunlight are found to vary approximately as the cosecant of the sun's altitude above the horizon. The light of the sun itself is practically the same at any given time and place year after year, but is liable to more or less local and temporary diminution by the amount of cloud, haze, dust, &c., present in the atmosphere at the time. It is also affected by the time of day, increasing from sunrise to noon, and then decreasing to sunset. The remaining factor is the effective diaphragm aperture of the lens in relation to its focal length. In most cases of ordinary outdoor exposures this can be taken at its normal value, but becomes smaller and increases exposure if the focal length is much increased for photographing near objects. Besides these principal factors, the nature and colour of the objects, their distance, and the amount of light received and reflected by them under various atmospheric conditions, have a great influence on the exposure required. W. B. Coventry has shown (*op. cit.* p. 75) how the "light coefficient L," for full sunlight, can be found, and has given a table of values of L for the latitude of London for every hour of the day in periods of ten days throughout the year, also the relative coefficients for "diffused light," "cloudy," "dull" and "very dull." Tables of exposures for different subjects under varying conditions of light have been published by W. K. Burton, A. S. Platts, F. W. Mills, Sir D. Salomons and others, and in preparing them Dr J. A. Scott's tables, showing monthly and daily variations of light for countries about N. lat. 53°, are generally used. The more modern tables, such as are published in the printed "exposure notebooks," also take into account the plate speeds, but unfortunately there is no uniform standard of plate speeds, owing to the difficulty of fixing a definite standard of light. The subject is fully treated in the *British Journal Almanac* (1901), p. 675, the *Watkins Manual*, H. Boursault's *Calcul du temps de pose en photographie*, and similar works by A. de la Baume Pluvinel, G. de C. d'Espinassoux and others.

Based on the same principle as these exposure tables, various portable exposure meters have been brought out, in which scales representing the coefficients for plate-speed, light and diaphragm are arranged as in a slide rule, so that, when properly set, the normal exposure required can be found by inspection, and increased or diminished according to circumstances. In Hurter and Driffield's "Actinograph" the light coefficient is given by a printed card showing the curves for every day in the year and for every hour of the day, the unit being the $\frac{1}{100}$ part of the brightest possible diffused daylight when the altitude of the sun is 90°. The "lens" scale shows the ratios of aperture to focal length in general use, and is calculated for single, double and triple systems of lenses. The "speed" scale is based on the exposure in seconds which with one actinograph degree of light will produce a perfect negative of an ordinary landscape. An additional scale is given for five different degrees of illumination—"very bright," "bright," "mean," "dull," "very dull." A table of factors for "views," "portraiture," "interiors," "copying," is also given, and these regulate the figure to be taken for the exposure. The scales are engraved on boxwood, and there are two sliding pieces (fig. 68). It is specially adapted for use with plates of speed numbers agreeing with the H. & D. scale, but can be used with any plate of which the relative speed number is known. Convenient exposure meters have been made since 1890 by A. Watkins, of Hereford, in different

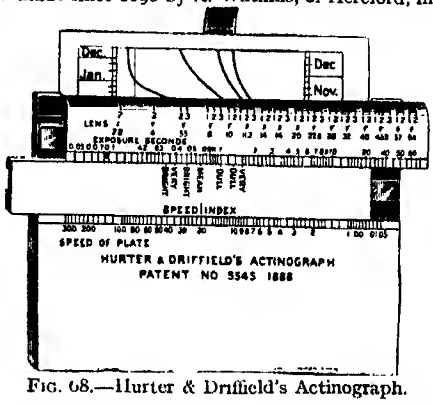

FIG. 68.—Hurter & Driffield's Actinograph.

forms based upon an actinometrical test of the light at the time of exposure. In the complete "Standard Meter" (1890) scales corresponding to "speed of plate," "diaphragm *f* numbers," "light," "subject" and "enlarging," marked P. D. A. S. and E., are arranged on rings adjustable round a cylinder. The plate-speeds are taken from a table and the "light coefficient," or "actinometer number," is ascertained at the time by exposing a piece of sensitive paper in the actinometer at the end of the instrument for the number of seconds required to match a fixed tint as shown by an attached pendulum. Many improvements have been made in it and the latest pattern (1908) is made in magnalium (fig. 69). The "Dial" meter (1901) is a simpler form in a circular metal case with four apertures marked "plate," "stop," "act" and "exp." above the corresponding scales, and an actinometer for testing the light. The numbers showing the speed of the plate in use, the *f* value of the diaphragm, and the actinometer exposure in seconds are brought into the respective apertures and the exposure required is read off in the "exposure" aperture.

FIG. 69.—Watkins's "Standard" Meter.

An "indoor meter" is also made, and a "hand camera calculator" for use with the "Standard" or "Bee" meters. The "Queen Bee" and "Bee" meters (1903) are later, smaller and more convenient patterns which have superseded the "Dial" meter and have the plate numbers and exposures marked round the case, and the scales of "*f* numbers" and "light" on a revolving glass plate. This is revolved till the *f* number on the right is opposite the speed number of the plate; opposite the "actinometer number" on the left, found as above, will be found the exposure in seconds (fig. 70). The "Queen Bee" meter is similar to the "Bee," but of better construction and fitted with a pendulum.

FIG. 70.—The Watkins's "Bee" Meter.

G. F. Wynne's "Infallible" exposure meter (1893) is also in dial form, but the sensitive paper is exposed directly, no pendulum is used, and the scales are open on the dial. In use, the glass carrying the movable scale is turned until the actinometer time in seconds upon the exposure scale is opposite the diaphragm number of the plate, as given in the list of plate speeds; the correct exposure will then be found against each stop given on the scale. There are practically only two scales: the scale of diaphragms representing the diaphragm apertures or *f* numbers, the speed of plate and the variation of exposure due to subject; and the time scale, representing the actinometer time and the exposure (fig. 71). The actinometer is protected by a yellow glass screen when not in use. In a smaller form the scales are on the

FIG. 71.—Wynne's "Infallible" Exposure Meter.

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

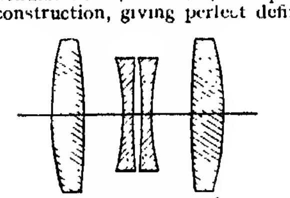

FIG. 53.—Beck-Steinheil "Unofocal."

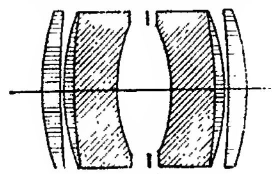

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

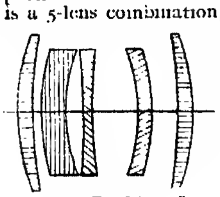

FIG. 55.—Beck's "Isostigmar."

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Bonie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Telediopt ricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

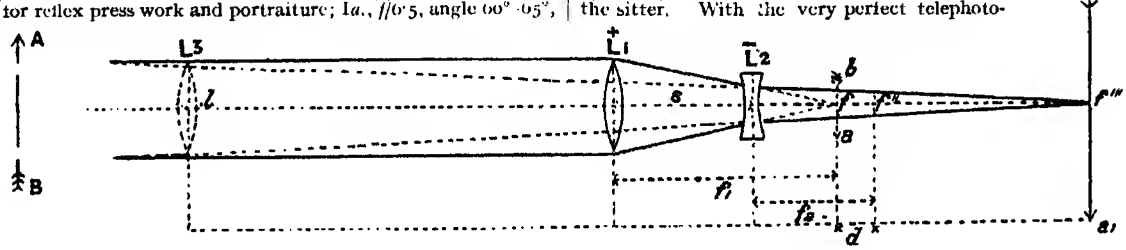

FIG. 56.

are remarkably good and practically solve the problem of direct colour photography in a simple and fairly inexpensive manner (see *Agenda Lumière*, 1909).

In C. L. Finlay's "Thames" colour plate (1908) the tricolour screen is formed by rows of circular dots coloured alternately orange-red and green and the intermediate spaces blue. It is used alone, the coated surface being placed in contact with a panchromatic plate, the uncoated side towards the lens. It carries register marks for adjusting it to the finished picture after development and reversal of the image. These screens, being more transparent than the "Autochrome," require less exposure, but the colour rendering is not so perfect. In the Jougla "Omnicolore" plate (1909) the tricolour screen and sensitive surface are combined on one plate as in the "Autochrome," but the screen is made up of a series of blue-violet parallel lines, with intermediate alternate broken lines of orange-red and yellowish-green at right angles to them, the red narrower than the green. The relative sizes of the coloured dots in the three plates are approximately:—

"Autochrome" starch grains . $\frac{1}{2500}$ to $\frac{1}{1750}$ in.
"Thames" plate, dots, diameter . . $\frac{1}{310}$ "
"Omnicolore" plates, blue line . . $\frac{1}{400}$ "
" " red square . . $\frac{1}{800}$ "

E. Fenske's "Aurora" plate (1909) is a tricolour screen formed by coating a glass plate with a mixture of finely divided particles of gelatin, dyed orange-red, green and blue-violet, without any intervening spaces. The grain generally is coarser and more irregular than in the "Autochrome" plates, but optically corresponds more closely to them than the "Thames" or "Omnicolore" screens do. These plates are issued uncoated for use with any suitable panchromatic plate. A later process is due to Dufay. With the exception of the "Autochrome," these processes are still more or less in the experimental stage.

Celluloid Films.—In order to avoid the weight of glass plates, which may become burdensome on a tour, and also the risk of breakage of valuable records, thin films or sheets of celluloid coated with sensitive emulsions can be used, with great saving of bulk and weight and no loss of efficiency, though such films are sometimes liable to deterioration by long keeping before or after exposure. They are made in two thicknesses, stiff or flexible, the stiff being used exactly as plates, but held in a carrier or simply backed with a card or glass plate, while the flexible are made up in separate sheaths with cardboard backing, as in the "Kodoid" films, or in convenient packages of twelve or more in "film packs" of various patterns. Flexible films of this kind on celluloid have for many years past also been prepared in long strips of different widths suitable for use in hand cameras of the Kodak types and in roll-holders. In the early forms of roll-holders the films were used alone, and being unprotected had to be changed in the dark room; but, as already stated, they are now supplied on spools in cartridges which can be changed in daylight. C. Silvy seems to have been the first to employ this method in 1870. In these cartridges the film is attached to a much longer strip of black paper, and rolled up with it, so that several turns of the paper have to be unrolled before the film is ready for exposure, this point being marked on the outside paper for the successive exposures, with numbers visible through a red screen at the back of the holder. When all have been exposed, the black paper is rolled on for several turns, and when taken out of the holder the loose end is fastened up till the film is developed. As these films are principally used for landscape work, it is now usual to make them isochromatic, and they may be used with or without a yellow screen. They are also made "non-curling" by being coated with gelatin on both sides. Negatives taken on these thin films have the advantage that they can be printed from either side without perceptible loss of definition, which is useful in printing by the single transfer carbon process, and in some of the photo-mechanical printing methods. Flexible transparent films in sheets and rolls have also been prepared upon hardened gelatin, but it is difficult to retain the original dimensions of the film owing to expansion of the gelatin. Paper coated with sensitive emulsions has been successfully used for making negatives in the same way as the celluloid films, and is cheaper, but much more liable to deterioration from atmospheric action before and after exposure, and unless developed soon after exposure the impressed images may fade and become undevelopable. Such papers are, however, still used in meteorological and other self-recording instruments. Stripping films of thin celluloid upon a paper support were introduced by Messrs Wellington and Ward, and had advantages for printing from either side, but are not now made.

Photographic Printing Papers.—*Pari passu* with the supply of ready-prepared plates, all kinds of photographic printing papers can now be obtained ready for use, so that the photographer has nothing to do with the preparation of his sensitive plates or papers. The old albuminized papers have been generally superseded by ready-prepared sensitive papers coated by machinery with emulsions of silver haloids in gelatin, with or without citrate or other organic silver salts, the chloride being used for most of the "P.O.P." or "printing out papers," which contain more or less free silver nitrate, and in the "self-toning" papers some salt of gold. Some of these printing out papers are also made with emulsions of silver chloride in collodion, and known as "C.C." or "collodiochloride." The basis of most of the developable bromide papers used for enlargements and direct copying, containing no free silver nitrate, and with which an invisible image is brought out by development, much in the same way as with dry plates, is silver bromide. These papers are made in great variety of tints and surfaces, "smooth" and "rough," "glossy" and "matt," for producing different effects. They are largely used for direct printing by artificial light or daylight, for enlargements, and for printing photographic post-cards, &c., in large numbers by machinery, the prints being made on a long band with an almost instantaneous exposure, and developed and fixed by being passed through the proper solutions on large rollers or otherwise. Papers for the platinotype processes, sensitized with salts of platinum and iron, are also manufactured for printing out entirely or for development with potassic oxalate. Prints on these papers have the advantage of being permanent.

Messrs York Schwartz and J. Mallabar's process of developing and toning prints made on a special sensitive paper prepared with an emulsion of silver phosphate was introduced by Messrs Houghton in 1908 under the name of "Ensyna." Very short exposures to day or artificial light are required, and with a special developer ("Ensynoid") permanent prints are obtained with a varied scale of tones similar to those given by toning with gold, the colour of the print being determined by the exposure, short exposures giving purple and long exposures brown or reddish tones. The process is a rapid one, the operations of printing, developing, fixing and washing being completed within about ten minutes or even less.

For the various methods of printing in permanent pigments ("Autotype," &c.) tissues are prepared coated with pigmented gelatin in various colours, and very successful results in colour photography have been obtained by printing from suitable negatives in three colours with specially prepared yellow, blue and pink tissues. Similar papers, prepared with pigmented gum instead of gelatin, are used in the "gum bichromate" process, and "single transfer" papers, coated with plain gelatin, are used in the pigment printing processes to receive the developed print, and are also useful for photo-lithography, the new "oil-printing" methods, and in trichromatic printing on paper by the Sanger-Shepherd method and Dr König's "Pinatype." For Manly's "Ozotype" and "Ozobrome" processes special gelatinized and pigmented papers are made. "Cyanotype" and "Ferrogallic" papers are prepared for the use of architects, engineers, &c., in rolls of considerable width, for the direct reproduction of tracings and drawings as blue or black prints by these and similar methods.

Apparatus for Development.—The recognition of the fact that the two principal factors in the development of modern photographic dry plates with a suitable developer are time and temperature, and also that a prolonged immersion in dilute solutions is in many cases a more convenient and equally efficient method of development, has led to the construction of apparatus for enabling the operation to be carried out almost automatically and for timing its duration.

In 1894 A. Watkins brought out his factorial system of development based on the principle "that with a correct exposure on a given plate with a given developing agent, the time of development required for a given printing opacity has a fixed arithmetical ratio to the time of appearance of the high lights of the image, provided the developing power of the solution remains constant during development; and this rule holds good for all variations of strength, amount of alkali or bromide, and temperature within those limits which have been found safe in practice" (*Photo. News*, 1894, 38, pp. 115, 729; and further, *Ph. Journ.*, 1900, 24, p. 221). By a series of observations he ascertained the multiplying factors of most of the developers in ordinary use, and in 1905 brought out his "factorial calculator" and a "dark-room clock" for facilitating the working of the method. The former is made of aluminium, and consists of two circular disks, the upper smaller one rotating and carrying a pointer. The outer disk is marked with a scale of Watkins's factors for the different developers, as given in the "instructions" accompanying the instrument, and is used to denote the "time of development" in minutes. The scale on the inner

Fig. 72.—Watkins's Factorial Calculator.

Fig. 73.—Watkins's Dark-room Clock.

disk shows the "time of appearance" in seconds or minutes. In use the pointer is set to the factor for the developer in use, and against the "time of appearance" on the inner scale will be found the total number of minutes required for complete development (fig. 72).

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

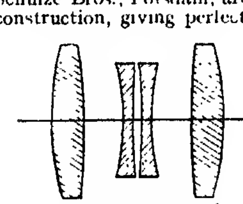

FIG. 53.—Beck-Steinheil "Unofocal."

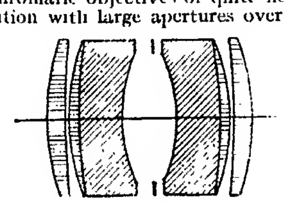

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=O$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°–65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

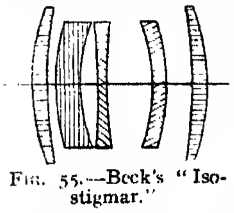

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Bonie and de Tournenire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Trabei also dealt with the question, and in J. Zahn's *Oculus artificialis Telediopticus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

III.—Pictorial Photography

Pictorial photography differs from other branches of photographic practice in the motive by which it is prompted. Employing the same methods and tools, it seeks to use photographic processes as a means of personal artistic expression. Thus in the early days of Fox Talbot's calotype, about 1846, David Octavius Hill, a successful Scottish painter, took up this method of portrayal, and, guided by an artist's knowledge and taste, and unfettered by photographic convention, which indeed had then scarcely begun to grow, produced portraits which for genuine pictorial quality have perhaps never been surpassed, especially if some allowance be made for the necessary imperfections of the "Talbotype" (see plate). Whether they were in their day typical examples of Talbotype with all the latest improvements, Hill probably never cared. When, again, a few years later, Sir William J. Newton, the eminent miniature painter, read a paper before the newly formed Photographic Society of Great Britain (now the Royal Photographic Society), his recommendation to depart from the custom of defining everything with excessive sharpness caused his address to be almost epoch-making. "I do not conceive it to be necessary or desirable," he said, "for an artist to represent, or aim at, the attainment of every minute detail, but to endeavour at producing a broad and general effect. . . . I do not consider that the whole of the subject should be what is called 'in focus'; on the contrary, I have found in many instances that the object is better obtained by the whole subject being a little out of focus." The doctrine has been persistently repeated ever since, but only within the last decade of the 19th century was the suppression or diffusion of focus received by photographers generally with anything better than ridicule or contempt, because it was unorthodox. O. G. Rejlander, Mrs Julia Margaret Cameron, H. P. Robinson, and others, by precept or practice, strove against such photographic conventions as had arisen out of those technical exigencies to which pictorial qualities were so often sacrificed. As late as 1868, in the *Manual of Photographic Manipulation*, by Lake Price, the old advice to arrange a group of persons in crescent form, so as to adapt the subject to the curve of the field of the lens, was repeated with the additional recommendation of plotting out on the ground beforehand the "curve of the focus" as a guide. As a defiance of this dictum, Rejlander, in 1869, produced a group of the members of the Solar Club in which some of the chief figures were set widely out of the "curve of the focus." The mere technical difficulties of this performance with wet collodion plates, and in an ordinary upper room, need not be touched upon here, but it is to be noted as one of those triumphant departures from convention which have marked the progressive stages of pictorial photography. At about the same period, Mrs Cameron, carrying the recommendation of "a little out of focus" rather further, regardless of how her lens was intended to be used by its maker, secured the rendering dictated by her own taste and judgment, with the result that many of her portraits, such as those of Tennyson, Carlyle, &c., are still in their way unsurpassed. Contemporaneously, Adam Salomon, a talented sculptor, "sunned" down the too garish lights of his photographic prints, and strengthened the high lights by working on the back of the negative.

But, during the concluding quarter of the 19th century, probably the most powerful influence in pictorial photography was that of H. P. Robinson, who died in February 1901, and, but for a brief period about the year 1875, was one of the most prolific "picture makers." Inspired by Rejlander, of whom he was a contemporary, Robinson will perhaps be best remembered by his earlier advocacy of combination printing. As early as 1855 Berwick and Annan exhibited a photograph which was the result of printing from more than one negative, a figure from one plate being cunningly introduced into a landscape print from another. Then came from Rejlander "The Two Ways of Life," in which, with wonderful ingenuity, thirty different negatives were combined. Robinson followed, and between 1858 and 1887 exhibited numerous examples of combination-printing, one of the most popular and fairly typical examples being "Carolling" (see plate), which received a medal in the exhibition of the Royal Photographic Society in 1887.

Though in this combination-printing one may perhaps perceive the germ of incentive towards the production of special effects not seen in the original, yet the practice was not destined to become very popular, for even in the most capable hands there remains the difficulty, if not impossibility, of fitting a portion of one negative into a print from another and still preserving true relative tonality, and even true proportion. Skilfully produced, eminently popular in character though "Carolling" may be, such errors are not absent. Of this combination-printing Dr P. H. Emerson has said: "Cloud printing is the simplest form of combination-printing, and the only one admissible when we are considering artistic work. Rejlander, however, in the early days of photography, tried to make pictures by combination-printing. This process is really what many of us practised in the nursery, that is, cutting out figures and pasting them into white spaces left for that purpose in the picture-book. With all the care in the world the very best artist living could not do this satisfactorily. Nature is so subtle that it is impossible to do this sort of patchwork and represent her. Even if the greater truths be registered, the lesser truths, still important, cannot be obtained, and the softness of outline is easily lost. The relation of the figure to the landscape can never be truly represented in this manner, for all subtle modelling of the contour of the figure is lost."

Pictorial photography received a large accession of votaries in consequence of the greater facilities offered by the introduction of the gelatino-bromide, or dry-plate, process, which, although dating from 1880, did not notably affect photographic communities until some years afterwards; and although improvement in appliances and instruments had little to do with the advance of the pictorial side of photography, yet, indirectly at least, the dry-plate and the platinotype printing process have had an undoubted effect. The former gave enormously increased facility, and dispensed with tedious manipulations and chemical knowledge, while its increased light-sensitiveness decreased the limitations as to subjects and effects. The platinotype process was discovered in 1874–1880 by W. Willis, who employed his chemical skill and knowledge to give the world a printing process more likely than the hitherto prevalent silver papers to satisfy artistic requirements.

Up to 1882 but few outdoor photographers had ventured to run counter to the general dictum that photographs should only be taken during sunshine or good bright light, and unquestioning

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

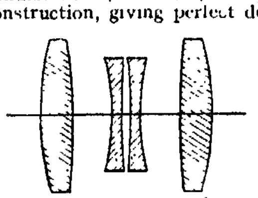

FIG. 53.—Beck-Steinheil "Unofocal."

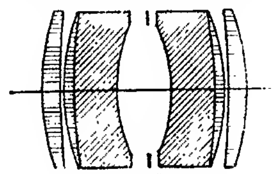

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°–65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

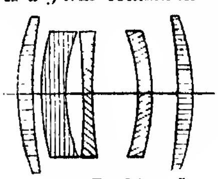

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Borie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

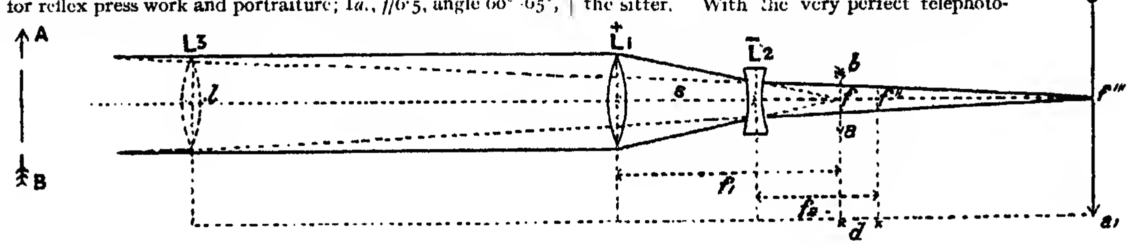

FIG. 56.

of luminousness to over-dark shadows and variety to blank whites. The almost forgotten process of Pouncy, and of Poitevin, now known as the gum bichromate process, was rehabilitated in 1894 by M. Rouille Ladeveze expressly to meet the needs of the pictorial worker. Perhaps the best results that have been achieved by it are those of M. Robert Demachy of Paris, though many English workers have used it with remarkable success. In it paper of any kind may be selected as the support. The power of the operator to modify the printed image to almost any extent, even to introducing and eliminating lights and shadows, and in other ways to depart widely from the image given by the negative, depends upon the fact that the coating of gum and pigment (which, being bichromatized, becomes insoluble in proportion as it is acted upon by light) holds the pigment but imperfectly, and yields it up upon a vigorous application of water. According, therefore, to its application or retention, the operator can lighten or deepen in tone any portion. Numberless variations of other methods, such as brush development and local toning or stopping, have been suggested with the same object. Other workers have shown that by dexterously shutting off and admitting the light to various parts of the negative whilst printing, the disposition of the lights and shades in the print can be modified to so great an extent as to alter the general contour of the scene. Examples of an original unaltered print, and one which has been thus modified, are shown in the accompanying plate. Portions are shaded in by allowing the light to have access to the print, either through the negative—in which case the image with all its details, prints more deeply—or by removing the negative, when the action of the light is to flatten and suppress both detail and contrast. Latterly some few have resorted to extensive working on the negative, both on the back and on the film; drawing by hand is practised on the film to render too prominent features less obtrusive, and objects in the background are merged by an intricacy of lines and cross-hatching. Many of the results are very pleasing, although one hesitates to justify the means, however good the end. On the other hand, to exclaim for purity of method and the exclusion of extraneous aids is very like setting up an arbitrary standard no less unreasonable than those conventions against which pictorial photography has so long striven.

PHOTOGRAPHY, CELESTIAL. The requisites for celestial photography are best explained by a comparison with ordinary photography in several essential points.

a. Illumination.—In taking a portrait artificial light is used, being thrown on to the face of the sitter either directly or by reflection. If the day is dull a longer exposure is required, and artificial light may be used when the daylight fails. In photographing the stars there is no question of illuminating them by artificial light; for the strongest searchlight which we could throw in the direction of the heavenly bodies would have no sensible effect. The light used is their own, and its feebleness renders it necessary to make long exposures, the length increasing as we attempt to get images of fainter objects. The invention of the dry plate, by making it possible to give very long exposures, caused a revolution in celestial photography. With the wet plate, exposures were limited to the few minutes during which the film would remain wet; but the dry plate can remain in the telescope for days, weeks or even years if necessary. On the approach of daylight, the cap is put on the camera, or the plate removed into the dark room; but when night returns the plate is put back in the telescope, which is accurately pointed to the same stars, the cap is removed, and the exposure is resumed without any loss from the interruption.

b. Magnification.—In taking a portrait we can obtain a large or small size by placing the camera near the sitter or far away. But this method is not available for the heavenly bodies, since we cannot sensibly approach them. To magnify an image we must lengthen the focus of the camera, either directly or indirectly. The *direct* method is to construct a lens or mirror of long focus; the camera becomes similar in length to a telescope; and indeed resembles a telescope in other respects, except that we take away the eye-piece and put in a photographic plate instead. If, however, we already have a lens of short focus which we wish to use, we may lengthen the focus *indirectly* by using a secondary magnifier, that is by putting in another lens near the focus of the first. In either case the profitable magnification is limited, not only by the imperfections of the optical apparatus but by disturbances in the atmosphere. Air currents, either outside or inside the telescope, act as irregular lenses of varying shape, and produce such defects in the image that we gain nothing by enlarging it beyond a certain point. Such air disturbances do not trouble the ordinary photographer at all, or scarcely at all: he is only concerned with a few feet of air, whereas the celestial photographer cannot escape from the necessity of looking through many miles of it.

c. Steadiness.—In taking a portrait the photographer is only concerned to fix his camera firmly and to induce his sitter to remain still. The heavenly bodies are in constant motion, though their real and apparent movements are fortunately smooth, except for air disturbances above mentioned. If, therefore, it were possible to devise perfectly smooth clockwork, we could keep the camera or telescope continually pointed to the required star or stars. But human workmanship has not yet made clockwork of sufficient strength and accuracy to keep a large telescope satisfactorily pointed. The clockwork which had been found good enough for use with visual telescopes was soon found to be quite inadequate for photography. The first method adopted was to bind two telescopes, one visual and the other photographic, firmly together; and by looking through the visual one to keep some object steadily on the crosswires by using the slow motion screws; meanwhile the other telescope was kept properly pointed for taking a photograph. As it was sometimes found that extremely fine movements were required, electrical arrangements were devised, whereby the observer, on simply pressing a button, could accelerate or retard the rate of the clockwork by a minute amount, instead of actually turning the screws by hand. And about the same time the idea arose of making these corrections automatically. This automatic correction is based on the principle that a freely swinging pendulum, which has no work to do, will naturally keep much better time than the clockwork which has to drive a heavy telescope; and if such a pendulum is therefore arranged to send a current every second through certain electro-magnets, apparatus can be devised to detect whether the clockwork is going properly; and to correct it in the right direction, if it is not. One or more of these three methods, which may be called hand-guiding, electrical control, and automatic electric control, are used in taking all celestial photographs.

The Photographic Image.—The image of a star on the plate should be, theoretically, merely a point; but in practice it is a small patch on the plate which grows in size as the exposure is lengthened, while at the same time it becomes darker in the middle. One reason for this is that light is many-coloured, and when we attempt to focus it by a lens, we can only get a very few colours into even approximate focus; the other colours are not brought to focus at all, and form concentric patches of fainter light on the plate, which increase in size with the error of focus. Thus at best our focusing is only a compromise. When the exposure is short, those colours which have most nearly been brought to focus have an effect, while the faint light of the others may produce no sensible impression. It is natural to select for the colours to be brought most sharply to focus those which are most important photographically, viz. those at the violet end of the spectrum. As the exposure proceeds the faint light of the other colours affects the plate by accumulation, and hence the image spreads, while at the same time the central part naturally becomes blacker.

A reflecting telescope brings all colours to the same focus; and it might appear, therefore, that images formed with it will not spread in this way. There is, however, another cause of spreading besides that due to colour; neither the reflecting telescope nor the lens can focus all the light received by them for more than one particular star. It is just theoretically possible to construct a mirror which would focus all the light from a star seen in the direction of its axis; but the light from another star seen in a slightly different direction would not be truly focused, since directly we leave the axis, some parts of the mirror have a focus slightly different from other parts; and if the image

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

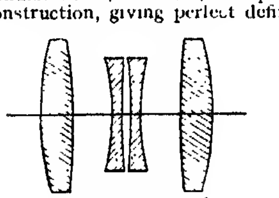

FIG. 53.—Beck-Steinheil "Unofocal."

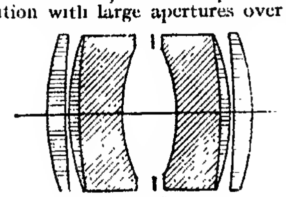

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=O$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Porro and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

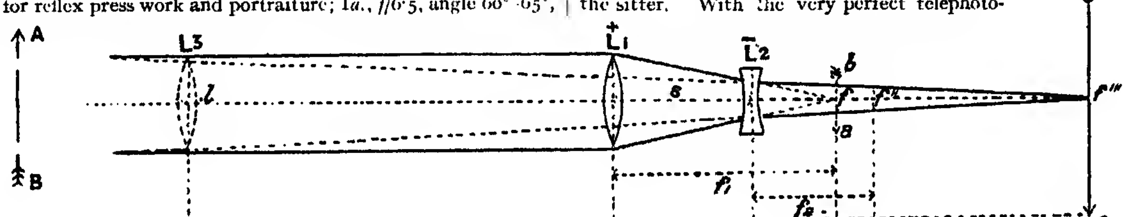

FIG. 56.

are well adapted to solution by least squares or any equivalent device.

Photography of Nebulae and Clusters.—Some of the earliest and most striking successes in celestial photography were the pictures of nebulae. Dr A. A. Common (1841–1903), F.R.S., of Ealing, led the way in 1883 with a successful picture of the great nebula in Orion, taken with a 3-ft. concave mirror by Calver. Dr Isaac Roberts (1829–1904) was the first to show the real structure of the great nebula in Andromeda, by a photograph also taken with a reflector. In the clear atmosphere of the Lick Observatory in California, small nebulae were photographed in great numbers by Professor J. E. Keeler (1857–1900): and it was shown what a large percentage were spiral in form. Prof. G. W. Ritchey, at the Yerkes Observatory, has followed up these successes with a 2-ft. reflector, and is constructing a 5-ft., to be erected on Mt Wilson (Cal.); but he has also shown that pictures of clusters are best taken with a telescope of long focus, such as the great Yerkes refractor; and incidentally that this telescope, although intended for visual work, can be adapted to photography by using a "colour screen" just in front of the plate, which sifts out the rays not brought to focus.

Photography of the Moon.—G. W. Ritchey has used the same device of a colour screen for the moon, and obtained even better pictures than those obtained at Paris, which were previously the best. The positions of a large number of craters and other points have been measured by Dr J. H. G. Franz and S. A. Saunder on photographs, and a new epoch in lunar topography has thereby been created.

Photography of the Planets.—Some striking successes have been obtained at the Lowell Observatory, Flagstaff, Arizona: by cutting down the aperture of the object-glass some of the delicate markings, called canals, on the planet Mars have been photographed; but even these do not approach what can be seen by the eye.

Photography of Comets.—Some wonderful pictures have been obtained of comets by Professor E. E. Barnard and others. Here, as in the case of nebulae, the photograph is superior to the eye in detecting faint luminosity, and delicate details of the tail structure have been photographed which could never be seen. In several pictures the tails have an appearance of violent shattering, and if successive pictures can be obtained at such times we may learn something of the nature of such disturbances.

Solar Photography.—The light of the sun is so intense that the chief difficulty is to obtain a short enough exposure. When successfully taken, photographs of the surface show the well-known spots and the mottling of the surface. The image sensibly falls off in intensity towards the limb, owing to the absorption of light by the solar atmosphere; and the bright faculae (which are thus inferred to lie above the main absorbing layer) are seen near the limb. But an immense advance in solar photography was made about a dozen years ago by the invention of the spectroheliograph, which is an instrument for photographing in the light of one very definite colour—say a single hydrogen line. The faculous appearances can be photographed with this instrument all over the sun's disk, instead of merely near the limb. The appearance presented varies enormously with the line selected, or (in the case of the wide "lines" in the spectrum, such as the H and K lines) with the particular part of the same line selected. But for a full account of such matters reference must be made to the articles SUN and SPECTROHELIOGRAPH.

PHOTOMETRY (from Gr. φῶς, φωτός, light, μέτρον, a measure), the art and science of comparing the intensities or illuminating powers of two or more sources of light. As in all scientific measurements, its methods are attempts to give quantitative accuracy to the crude comparisons made by the eye itself. The necessity for this accuracy in practical affairs of life has arisen because of the great development of artificial lighting in recent times. The eye soon learns to associate with any particular source of light a quality of brightness or power of illumination which diminishes with increase of distance of the source from the eye or from the surface illuminated. This quality depends upon an intrinsic property of the source of light itself, generally known as its "candle power." The aim of photometry is to measure this candle power; and whatever be the experimental means adopted the eye must in all cases be the final judge.

In the photometric comparison of artificial lights, which frequently vary both in size and colour, direct observation of the sources themselves does not yield satisfactory results. It is found to be much better to compare the illuminations produced on dead white surfaces from which no regular reflection takes place, or through colourless translucent material uniformly illuminated by the light placed on the further side. By such processes there is always loss of light, and we must be certain that the various coloured constituents of the light are reduced in the same proportion. This necessary condition is practically satisfied by the use of white diffusing screens.

Inverse Square Distance Law.

Two principles of radiation underlie many photometric applications, namely, the inverse square distance law, and J. H. Lambert's "cosine law." Both can be established on theoretical grounds, certain conditions being fulfilled. But as these conditions are never absolutely satisfied, the applicability of the two laws must in the end be tested by experiment. Since we find that within the errors of observation four candles, placed together at a distance of 2 ft. from a diffusing screen, produce the same illumination as one candle at a distance of 1 ft., we may regard the inverse square distance law as satisfied. Thus if two lights of intensities A and B produce equal illuminations on a screen when their distances from the screen are respectively a and b, we at once write down the relation between the two intensities in the form $A:B=a^2:b^2$. The theoretical basis of the law follows at once from the universally accepted view that light is energy radiating outwards in all directions from the source. If we assume that there is no loss of energy in the transmitting medium, then the whole amount of radiant energy passing in one second across any closed surface completely surrounding the source of light must be the same whatever the size or form of the surface. Imagine for simplicity a point source of light, or its equivalent, a uniformly radiating spherical surface with the point at its centre, and draw round this point a spherical surface of unit radius. Across this surface there will pass a definite amount of radiant energy, in other words a definite total luminous flux, E, which will be the same for all concentric spherical surfaces. Since the area of a spherical surface of radius r is $4\pi r^2$, the flux which crosses unit area is $E/4\pi r^2$. This quantity is the "illumination." It is measured in terms of the unit called the *lux*, which is defined as the illumination produced by a light of unit intensity on a perfectly white surface at a distance of 1 ft. In the great majority of photometers the illuminations are compared, and the intensities are deduced by applying the law of the squared distances.

Lambert's Cosine Law.

Lambert's cosine law has to do with the way in which a luminous surface sends off its radiations in various directions. It is a matter of common observation that the disk of the sun appears equally bright all over the surface. Careful measurements show that this is not strictly true; but it is sufficiently near the truth to suggest that under certain definable conditions the law would hold accurately. Again, when a glowing surface is viewed through a small hole in an opaque plate, the brightness is very approximately independent of the angular position of the incandescent surface. This is the same phenomenon as the first mentioned, and shows that the more oblique, and therefore larger, element of surface sends the same amount of radiation through the hole. Hence the amount per unit surface sent off

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°–65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

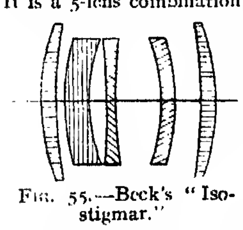

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1860 by MM. Borie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

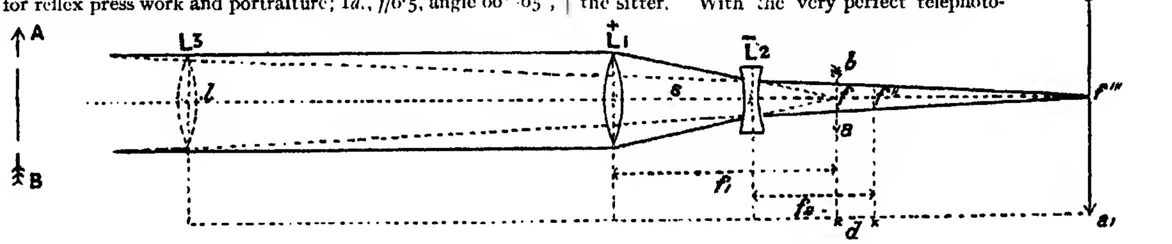

FIG. 56.

photometer. The earlier forms of photometers were very simple and not capable of giving very precise results. The principles of construction are, however, the same in all the recognized forms down to the most elaborate of recent inventions. Two of the earliest forms were described by P. Bouguer and W. Ritchie. The Ritchie wedge constitutes the basis of many varieties of type. The two lights to be compared illuminate the sides of the wedge, which is placed between them, so that the eye set in front of the wedge sees the two sides illuminated each by one of the lights. The edge should be as sharp as possible so that the two illuminated surfaces are in close contact. The illuminations are made equal either by shifting the wedge along the line joining the lights or by moving one of the lights nearer to or farther from the wedge as may be required. The lights given out by the sources are then as the squares of the distances from the matched parts of the surfaces. Count Rumford suggested the comparison of the intensity of the shadows of the same object thrown side by side on a screen by the two lights to be compared. In this case the shadow due to one source is lit up by the other alone; and here again the amounts of light given out by the sources are as the squares of their distances from the screen when the shadows are equally intense. The shadow-casting object should be near the screen, so as to avoid penumbra as much as possible; yet not too near, so that the shadows may not overlap.

Photometers.

Ritchie's Wedge.

Rumford's Photometer.

R. Bunsen suggested the very simple expedient of making a grease-spot on white paper for photometric purposes. When the paper is equally illuminated from both sides the grease-spot cannot be seen except by very close inspection. In using this photometer, the sources are placed in one line with the grease-spot, which lies between them and can be moved towards one or other. To make the most accurate determinations with this arrangement the adjustment should first be made from the side on which one source lies, then the screen turned round and the adjustment made from the side of the other source—in both cases, therefore, from the same side of the paper screen. Take the mean of these positions (which are usually very close together), and the amounts of light are as the squares of the distances of the sources from this point. The efficiency of the Bunsen photometer has been improved by using two inclined mirrors so that the eye views both sides of the paper simultaneously.

Bunsen's Photometer.

Sir Charles Wheatstone suggested a hollow glass bead, silvered internally, and made to describe very rapidly a closed path, for use as a photometer. When it is placed between two sources we see two *parallel* curves of reflected light, one due to each source. Make these, by trial, equally bright; and the amounts of light from the sources are, again, as the squares of the distances.

Wheatstone's Photometer.

William Swan's prism photometer, invented in 1859, is a beautiful application of the principle embodied in Bunsen's grease-spot photometer (see *Trans. Roy. Soc. Ed.*, vol. xxi.). The essential part of the instrument is fundamentally the same as that described by O. Lummer and E. Brodhun in 1889. It consists of two equal right-angled isosceles glass prisms placed with their diagonal faces together so as to form a cube (fig. 1), and cemented together by a small patch of Canada balsam, which spreads out into a circle when the prisms are pressed together. In the figure, which represents a central section of the bi-prism, the Canada balsam is represented by the letter N. The light from two illuminated surfaces, PQ, RS, is allowed to fall perpendicularly on the faces AB, AD. In each case that part of the light falling internally on the portion of the diagonal face which is not backed with the Canada balsam is totally reflected. On the other hand, the light which falls on the portion backed by the Canada balsam is almost wholly transmitted. Thus an eye placed in the position *qtp* receives light from both sources, the surface RS supplying nearly all the light that seems to come from the patch N, and the surface PQ supplying all the light which seems to come from the region immediately surrounding N. The patch N will in general be visible; but it will quite disappear when the luminosity of the ray *Tt*, which traverses the Canada balsam, is exactly equal to the luminosity of the rays *Pp*, *Qq*, which have come after total reflection from the surface PQ. This condition of invisibility of N is arrived at by adjusting the positions of the sources of light which illuminate the surfaces PQ, RS. The brightnesses of the two sources will then be as the squares of their distances from their respective screens.

Swan's Double Prism.

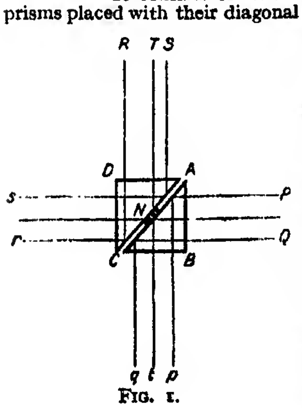

FIG. 1.

The essential part of Lummer and Brodhun's photometer is a combination of prisms very similar to Swan's. In its most improved form the bi-prism or "optical cube" has one of its component prisms cut in a peculiar manner. The diagonal face is partly cut away, so that the central part only of this face can be brought into contact with the diagonal face of the other prism. The Canada balsam is dispensed with, the surfaces being pressed closely together so that no layer of air is left between them. In order to make the instrument convenient for use with an optical bench, Lummer and Brodhun make the illuminated surfaces which are to be compared the opposite sides of an opaque screen set in the continuation of the diagonal (CA) of the bi-prism, the rays being brought by reflection from symmetrically situated mirrors so as to enter the sides AB and AD perpendicularly. An important modification, due also to Lummer and Brodhun, is the following: By means of a sand-blast a portion, which may be called *r*, is removed from one half of the diagonal face of the one prism, and from the other half of the same prism there is removed in like manner all but a part *l* corresponding to the part *r*. The portions which have not been removed are pressed close to the diagonal face of the other prism, and become the parts through which light is freely transmitted. On the other hand, the light which enters the second prism and falls on the portions of surface backed by the layers of air filling the cut-out parts is totally reflected. The general result is the production of two similar luminous patches *l* and *r*, each of which is surrounded by a field of the same intensity as the other patch. When the photometric match is made the whole region will be uniformly bright. But, by insertion of strips of glass so as to weaken equally the intensity in the surrounding fields, the match will be obtained when these fields are made of equal intensity and when at the same time the two patches differ equally in intensity from them. Under these conditions the eye is able to judge more certainly as to the equality of intensity of the two patches, and an untrained observer is able to effect a comparison with an accuracy which is impossible with most forms of photometer.

Lummer and Brodhun's Photometer.

J. Joly's diffusion photometer consists of two equal rectangular parallelepipeds of a translucent substance like paraffin separated by a thin opaque disk. It is set between the sources of light to be compared in such a way that each paraffin block is illuminated by one only of the sources, and is adjusted until the two blocks appear to be of the same brightness. The method is made more sensitive by mounting the photometer on an elastic vibrator so as to render it capable of a slight to-and-fro oscillation about a mean position.

Joly's Photometer.

A form of photometer which is well adapted for measuring the illumination in a region is that due to L. Weber. It consists of a horizontal tube across one end of which is fitted another tube at right angles. This second tube can be rotated into any position perpendicular to the horizontal tube. Where the axes of the two tubes meet is placed in the later forms of the instrument one of Lummer and Brodhun's modified Swan cubes. At the other end of the horizontal tube a standard flame is set illuminating a piece of ground glass which may be moved to any convenient position in the tube. The eye looks along the cross tube, at the farther end of which is placed another piece of ground glass illuminated from the outside. The illuminations of the two pieces of ground glass as viewed through the photometer double prism are brought to equality, either by shift of the ground glass to or from the standard light, or by means of two Nicol prisms placed in the cross tube. One advantage of the instrument is its portability.

Weber's Photometer.

The photometry of incandescent electric lamps has led to several special modifications and devices. The candle power varies distinctly in different horizontal directions, and one measurement in any particular direction is not sufficient. Sometimes the lamp is rotated about three times a second about a vertical axis and an average value thus obtained. But there is always a risk of the filament breaking; and in all cases the effect of centrifugal force must alter the form of the filament and therefore the distances of the different parts from the screen. Accuracy demands either the measurement of the radiation intensity in a number of directions all round the lamp, or one combined

Incandescent Electric Lamp.

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

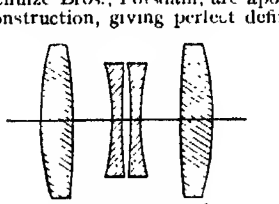

FIG. 53.—Beck-Steinheil "Unofocal."

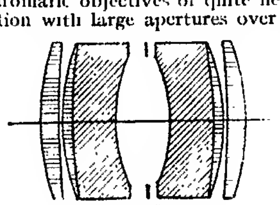

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f) = 0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

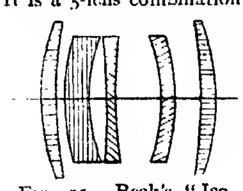

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1860 by MM. Porro and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

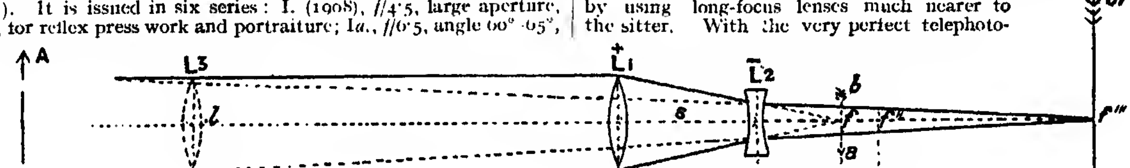

FIG. 56.

in a peculiar manner. The sharp edge, which passes slightly obliquely across the rim from one side of the wheel to the other and back again, is the meeting of two exactly similar conical surfaces facing different ways and having their axes parallel to, but on opposite sides of, the axis of rotation of the wheel. As the wheel rotates with its rim facing the eye, the intersection of the two surfaces crosses and recrosses the line of vision during each revolution. Hence first the one illuminated side and then the other are presented to the eye in rapid alternation. The inventors of this instrument claim that their instrument can gauge accurately and easily the relative intensities of two lights, whether of the same or of different colour (*Phil. Mag.*, 1904). There is no doubt that results obtained by different observers with a flicker photometer are in better agreement than with any other form of photometer. The comparative ease with which the balance is obtained even when the tints are markedly different shows that its action depends upon a visual distinction which the eye can readily appreciate, and this distinction is mainly one of brightness.

The spectrophotometer is an instrument which enables us to make photometric comparisons between the similarly coloured portions of the spectra of two different sources of light, or of two parts of the same original source after they have passed through different absorbing media. When it is desired to compare the intensities of the spectra from two different sources a convenient form is the one described by E. L. Nichols. A direct vision spectroscope mounted upon a carriage travels along a track between the two sources. In front of the slit two right-angled triangular prisms are set so that the light from each source enters the one side of one prism perpendicularly and is totally reflected into the spectroscope. The two spectra are then seen side by side. Attention being fixed on some chosen narrow portion, say, in the green, the instrument is moved along the track between the sources until the two portions appear of the same intensity. The process is then repeated until the whole spectrum has been explored.

Spectrophotometry.

In Lummer and Brodhun's form of spectrophotometer the rays to be compared pass in perpendicular lines through the modified Swan double prism, and then together side by side through a spectroscope. By means of a simple modification in the form of the two prisms, Professor D. B. Brace (*Phil. Mag.*, 1899) made the combined prism serve to produce the spectra as well as to effect the desired comparison. In this arrangement the compound prism A B C (fig. 2) is made up of two equal right-angled prisms ADB and ADC placed with their longer sides in contact, so that the whole forms an equilateral prism with three polished faces. Part of the interface AD is silvered, the silvering forming a narrow central strip running parallel to AD. Along the rest of the interface the two prisms are cemented together with Canada balsam or other material having as nearly as possible the same refractive index as the glass. When two rays R S enter symmetrically from opposite sides of the base of the compound prism as shown in the diagram, the ray R will pass through the prism except where the silver strip intercepts it, and will form a part of a spectrum visible to the eye placed at R′, while to the same eye there will be visible the similarly dispersed ray SS′ reflected from the silvered surface. Thus two systems of incident parallel rays of white light will form on emergence two spectra with corresponding rays exactly parallel. With these and other forms of instrument the aim of the experimenter is to make the two spectra of equal intensity by a method which enables him to compare the original intensities of the sources. In most cases the relative intensities of the portions of the spectra being compared cannot conveniently be altered by varying the distances of the sources. Recourse is therefore generally had to one of the other methods already mentioned, such as the use of polarizing prisms or of rotating sectors. Under certain conditions K. Vierordt's method of allowing the two rays to pass through slits of different width leads to good results, but too great confidence cannot be placed upon it.

Brace's Spectrophotometer.

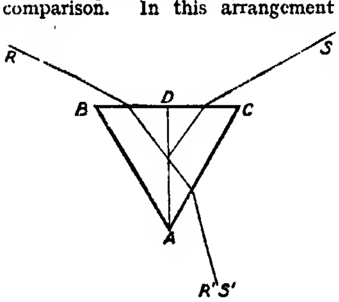

FIG. 2.

In other types of spectrophotometer, such as those associated with the names of H. Trannin, A. Crova, H. Wild, G. Hüfner, J. Königsberger, A. König, F. F. Martens and others, the equalization in brightness of two rays is effected by using polarized light, which can be cut down at pleasure by rotation of a Nicol prism. For example, in the König-Martens instrument the two rays which are to be compared enter the upper and lower halves of a divided slit. After passing through a lens they pass in succession through (1) a dispersing prism, (2) a Wollaston prism, (3) a biprism, and are finally focused where the eight spectra so produced can be viewed by the eye. Of these only two are made use of, the others being cut out. These two are polarized in perpendicular planes, so that if between the spectrum images and the eye a Nicol prism is introduced the intensities of any two narrow corresponding portions of the two spectra can be readily equalized. In terms of the angle of rotation of the Nicol the relative intensities of the original rays can be calculated. An important application of the spectrophotometer is to measure the absorptive powers and extinction coefficients of transparent substances for the differently coloured rays of light. By appropriate means the intensities of chosen corresponding parts of the two contiguous spectra are made equal—in other words, a match is established. Into the path of the rays of one of the spectra the absorbent substance is then introduced, and a match is again established. A measure of the loss of luminosity due to the interposition of the absorbent substance is thus obtained.

Konig-Martens's Spectrophotometer.

To facilitate experiments of this nature Dr J. R. Milne has devised a spectrophotometer which presents some novelties of construction (see *Proceedings of the Optical Convention*, 1905, vol. i.). The light from a bright flame is suitably projected by a lens so as to illuminate a small hole in the end of the collimator. The rays from this point-source are made parallel by the collimator, and then pass, partly through the absorbing medium, partly through the space above it. These two parts of the original beam are transmitted through a dispersing prism and then fall upon a screen with two similar rectangular openings, the upper one allowing the unabsorbed part of the beam to pass, the lower that part which has been transmitted through the absorbing medium. The objective of the observing telescope converges the rays suitably upon a Wollaston prism, so that two spectra are seen side by side, having their light polarized in perpendicular planes. A Nicol prism is placed between the Wollaston prism and the eye-piece of the telescope, and by its rotation in the manner already described the intensities of any two corresponding portions of the two spectra can be brought to equality. By careful attention to all necessary details Milne shows that his instrument satisfies the requirements of a good spectrophotometer; for (1) the rays through the absorbing medium can be made strictly parallel; (2) the two spectra can be brought with ease accurately edge to edge without any diffraction effects; (3) the plane of the delimiting screen can be made conjugate to the retina of the observer's eye; (4) not only do the two spectra touch accurately along their common edge, but the two fans of rays which proceed from every point of the common edge lie in one and the same plane; (5) the eye is called upon to judge the relative intensities not of two narrow slits but of two broad uniformly illuminated areas. Milne also points out that this instrument can be used as a spectropolarimeter.

Milne's Spectrophotometer.

E. L. Nichols considers that spectrophotometers which depend for their action upon the properties of polarized light are necessarily open to serious objections, such as: selective absorption in the calcspar, altering the relative intensities of the constituents in the original rays; selective losses by reflection of polarized rays at the various optical surfaces; and the necessarily imperfect performance of all forms of polarizing media. To eliminate these defects as far as possible great care in construction and arrangement is needed, otherwise corrections must be applied.

It is evident that if the successive parts of two spectra are compared photometrically we may by a process of summation obtain a comparison of the total luminosities of the lights which form the spectra. This process is far too tedious to be of any practical value, but sufficiently accurate results may in certain cases be obtained by comparison of two or more particular parts of the spectra, for example, strips in the red, green and blue. Similar in principle is the method suggested by J. Macé de Lepinay, who matches his lights by looking first through a red glass of a particular tint and then through a chosen green. If R and G represent the corresponding ratios of the intensities, the required comparison is calculated from the formula $I = \dfrac{R}{1 + 0{\cdot}208\,(1 - GR)}$. A. Crova, one of the earliest workers in this subject, effects the photometric comparison of differently coloured lights by matching those monochromatic rays from the two sources which have the same ratio of intensities as the whole collected rays that make up the lights. Careful experiment alone can determine this particular ray, but were it once ascertained for the various sources of light in use the method would have the merits of rapidity and accuracy sufficient for

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

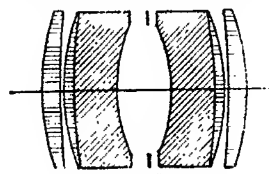

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

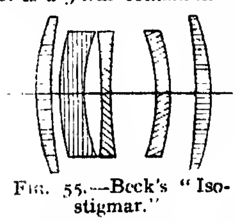

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Bonie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice*, *Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

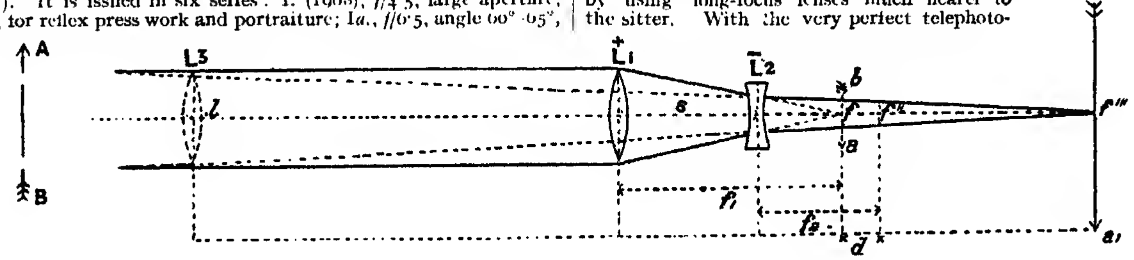

FIG. 56.

would be absolutely fixed and would constantly reflect the light of this star down the axis of its telescope; in practice a slight motion can be given to the mirror so as to keep in view the polar star selected, whether Polaris, with which the brighter stars were compared, or λ Ursae Minoris, which was used for fainter stars. The second mirror (which projects a little beyond the first so as to get an unobstructed view of the meridian) can be rotated round the axis of the telescope by means of a toothed-wheel gearing, and can thus be made to reflect any star on the meridian down the second telescope; it is also provided with a small motion in the perpendicular direction, so as to command a degree or two on each side of the meridian. Near the common eyepiece of the telescopes there is a double image prism which separates the light received from each into two pencils; the pencil of ordinary rays from one object-glass is made to coincide with that of extraordinary rays from the other, and the two remaining pencils are excluded by a stop. The two coincident pencils then pass through a Nicol prism to the eye of the observer, who by rotating the prism round its axis can equalize them at a definite reading depending on their relative intensities. This reading gives in fact the difference of magnitude between the two stars selected for comparison. It may be remarked that the position of the double image prism is important. It should be just *within*, not *at*, the common focus: this position prevents any noticeable colour in the images, and gives the ordinary and extraordinary pencils a sufficient separation at the eye-stop to permit the entire exclusion of one without the loss of any part of the other. If the prism were exactly at the focus, and any part of the superfluous images were admitted, the resulting secondary images would coincide with the others and thus lead to errors in observing. But in the actual construction of the instrument the secondary images would appear, if at all, only as additional stars near those under observation, and too faint to produce any inconvenience. It is worthy of note that Professor Pickering has extended his survey into the southern hemisphere, so that the Harvard photometry is the most complete of all. Each observation consists of four comparisons; after the first two the observer reverses the position of the star images in the field, and also reverses the double image prism. The former precaution is necessary in order to eliminate a curious error depending on the relative position of the images, which may amount to several tenths of a magnitude. Errors of this kind affect *all* estimations of the relative brightness of two stars in the same field, as has been repeatedly shown; a striking instance is given by A. W. Roberts, of Lovedale, South Africa (*Mon. Not. R.A.S.*, April 1897), who found that his eye-estimations of the brightness of variable stars required a correction depending on the position-angle of the comparison star ranging over nearly two magnitudes.

Pickering's Meridian Photometer.

In Zöllner's instrument an artificial star is taken as the standard of comparison. There is only one telescope, and inside the tube near the eye end is a plate of glass placed at an angle of 45° with the axis, so that the rays from a lamp which enter the tube from the side are reflected down the tube to the eyepiece, while the light from the star passes through the plate unobstructed. The lamplight passes through a Nicol prism and a plate of rock crystal, which give control over the colour; through two Nicols which can be rotated round the axis of the beam to definite positions read off on a graduated circle; and then through a convex lens which forms an image reflected by the glass plate to focus alongside the star. The whole of this apparatus is carried in a compact form on the eye end of the telescope, it being arranged that the lamp shall always stand upright. The measures are made by rotating the Nicols until the brightness of the artificial star is equal to that of the star viewed through the object glass, and reading the graduated circle.

Zöllner's Photometer.

Professor Pritchard's (1808–1893) wedge photometer is constructed on the principle that the absorption of light in passing through a uniform medium depends, *caeteris paribus*, upon the thickness. On this principle a thin wedge is constructed of homogeneous and nearly neutral-tinted glass, through which the images of stars formed in the focus of a telescope are viewed. Simple means are contrived for measuring with great exactness the several thicknesses at which the light of these telescopic star-images is extinguished. In this way the light of any star can be readily compared with that of Polaris (or any other selected star) at the moment of observation, and thus a catalogue of star-magnitudes can be formed. Two material improvements suggested by Dr E. J. Spitta are worthy of notice. The first (*Proc. Roy. Soc.*, 1889, 47, 15) corrects a slight defect in the form of the instrument. If a pencil of rays passes through a thin wedge of tinted glass, the rays do not all pass through the same thickness of glass. Dr Spitta proposes to substitute a pair of wedges with their thicknesses increasing in opposite directions. By sliding one over the other we obtain a parallel plate of glass of varying thickness, and a uniform beam of light of sensible dimensions can then be extinguished satisfactorily. He has also pointed out a source of error in the method of "evaluating" the wedge and shown how to correct it. The scale value was determined by Professor Pritchard by the use of a doubly refracting prism of quartz and a Nicol prism. Using this method subsequently, Dr Spitta found that internal reflections within the Nicol prism interfered with the accuracy of the result, but that this error could be eliminated by using a suitable diaphragm (*Mon. Not. R.A.S.*, March 1890; Abney, ibid., June 1890).

The Wedge Photometer.

Since 1885 systematic catalogues of stellar brightness have been constructed with all these instruments, and it has been of great interest to compare the results. The comparison has in general shown a satisfactory agreement, but there are small differences which are almost certainly systematic, due to the difference of method and instrument. One cause of such differences, the reality of which is undoubted, but the effects of which have as yet not been perhaps fully worked out, is the "Purkinje phenomenon" (*Pflügers Archiv.* lxx. 297). If a blue source of light and a red source appear equally bright to the eye, and if the intensity of each be diminished in the same ratio, they will no longer appear equally bright, the blue now appearing the brighter; in more general terms, the equalizing of two differently coloured lights by the eye depends upon their intensity. It is clear that this phenomenon must affect all photometric work unless the stars are all exactly of the same colour, which we know they are not. For let us suppose that both the comparison star of the meridian photometer and the artificial star of the Zöllner photometer were equalized with a bright star A, and that they could be also compared *inter se* and found equally bright. Then when a faint star B comes under observation and the intensities of the comparison stars are both reduced to equality with B, they will no longer appear equal to one another unless they are exactly the same in colour. In other words, the observed ratio of intensities of A and B will vary with the colour of the comparison star, and similarly it will also vary with the aperture of the telescope employed. Now it is one of the merits of the Potsdam catalogue above mentioned that it gives estimates of the colours of the stars as well as of their magnitudes—so that we now for the first time have this systematic information. In a most interesting section of their introduction it is shown that two of the Harvard photometric catalogues show systematic differences, due to colour, and amounting to nearly half a magnitude; and that the Purkinje phenomenon is a satisfactory explanation of these differences. This is the first instance in which the effect of this phenomenon has been measured in the case of the stars, though it was known to be sensible. But there is a set of numerical results obtained in the laboratory which is of importance for all such works, viz. those obtained by Sir W. Abney (*Proc. Roy. Soc.*, May 1891; and *Mon. Not. R.A.S.*, April 1892), giving the limiting intensity at which each pure colour vanishes. If we start with lights C D E F G of the colours usually denoted by these letters in the spectrum, and each so bright that it appears *to the eye* as bright as an amyl-acetate lamp at 1 ft., and if then the intensity of each be gradually diminished, the C light will disappear when the original intensity has been reduced to 22,000 ten-millionths of the original value. The other colours will disappear at the following intensities, all expressed in ten-millionths of the original: D at 350, E at 35, F at 17, and G at 15. If then we had a mixture of two lights, one of C colour as bright as before, and the other of G colour 1000 times fainter (a combination in which the eye would be unable to distinguish the G light at all), and if we continually reduced the combined intensity, the luminosity of the C light would diminish so much more rapidly than that of the G that the latter would begin to assert itself, and when the combined intensities were reduced to 22,000 ten-millionths of the original value, the C light would have all disappeared, while the G light would not. Hence the colour of the light would appear pure violet, though it was originally deep red. This extreme case shows that the "last ray to disappear" when a light is gradually extinguished may be very different in colour from that of the original light, and when more usual light-mixtures are considered, such as those of sunlight and starlight, which appear nearly white to the eye, the "last ray to disappear" is found to be in the green, very near E in the spectrum. This result has two important bearings on the use of the wedge photometer. In the first place,

The Purkinje Phenomenon.

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

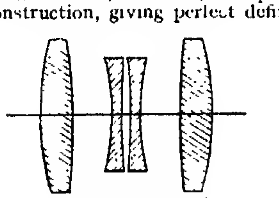

FIG. 53.—Beck-Steinheil "Unofocal."

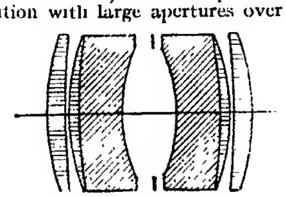

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f) = 0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

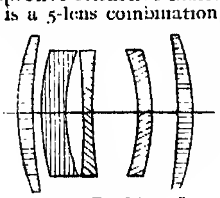

FIG. 55.—Beck's "Isostigmar."

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Porro and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

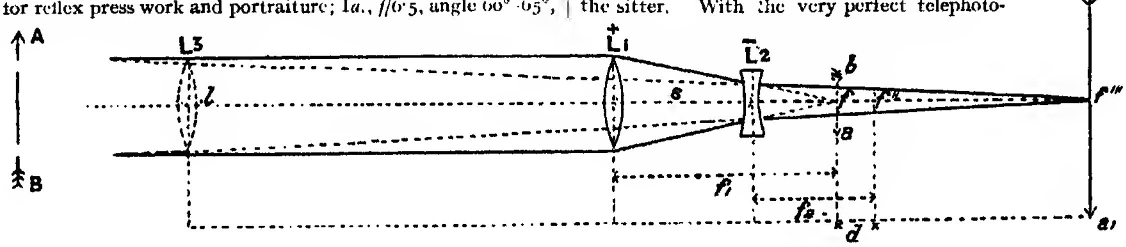

FIG. 56.

of the moon. Other experiments followed, and the average of all the results was that the light of the sun was about 300,000 times the average light of a full moon, both being viewed in the heavens at the same altitudes. The details will be found in Bouguer's *Traité d'optique.* W. H. Wollaston in 1829 tried a series of experiments in which the ratio 801,072 was obtained; but the omission of certain necessary precautions vitiates the result (*Phil. Trans.*, 1829). Bond (*Mem. Amer. Acad.*, 1861, p. 295) adopted a different process. He formed the image of the sun on a silvered globe of some 10 in. diameter; the light of this image was reflected on to a small mercurial thermometer bulb; and then this second image was compared with a Bengal light so moved that the lights appeared to be equal. The same process was adopted with the full moon instead of with the sun. The result was that the sun's light was 470,980 times that of the moon. Seidel long before this date had compared the light of the mean full moon with that of Jupiter in mean opposition; his result is 6430. So also this light of Jupiter was found to be ·4864 times that of Venus at her brightest; and Jupiter was found to give 8·2 times the light of α Lyrae. If, then, these numbers could be accepted with confidence, we should have the means of comparing the light received from the sun with that received from any of the stars. Adopting these precarious numbers on the authorities of Bond and Seidel we have the following results:—

Sun's light	=	470,980	that of the full moon.	
„	=	622,000,000	„	Venus at her brightest.
„	=	302,835,000	„	Jupiter at mean opposition.
„	=	5,970,500,000	„	Sirius.

Lastly, Bouguer, by comparing the light of the full moon viewed at different altitudes with an artificial light, found that the atmosphere absorbs ·1877 of the light incident on it at the zenith of any place. Professor Pritchard, from photometric measures taken at Cairo, found this number to be ·157. At Oxford it was ·209. Thus Bouguer's determination indicates an absorptive capacity in the atmosphere of Brittany just midway between those of Oxford and Cairo. Seidel at Munich expresses "surprise" at finding his own results so nearly accordant with Bouguer's. Although rather outside the domain of photometry in the strict sense, a word or two may be said here about recent attempts to measure the heat received from the stars, the first being made with the "radio-micrometer" of C. V. Boys (*Proc. Roy. Soc.*, 1890). This is an extremely delicate instrument for measuring radiant heat, and consists of a very light thermo-electric circuit (two tiny bars of antimony and bismuth soldered together at one edge, the outer edges being connected by a hoop of copper wire) suspended by a quartz fibre (a torsion fibre of the very greatest sensitiveness) in a strong magnetic field. A minute quantity of radiant heat falling on one of the junctions of the circuit sets up a current in the circuit, which thus rotates in the magnetic field until brought to rest by the torsion of the fibre. For use on the heavenly bodies the radiant heat is collected to focus by a reflecting telescope (an object-glass would absorb it), and when the telescope is pointed to the moon the varying radiation from different parts of the disk is beautifully shown. No heat comes from the unlit portion, and of the illuminated portion the maximum is obtained from near the limb. But when pointed to the brightest stars no indications were obtained, although the instrument is sensitive enough to detect the heat from a candle more than a mile off. It seems certain that indications of heat from the stars obtained by previous observers must be spurious. It is also manifest that to obtain satisfactory results even more sensitive apparatus must be devised, and by using a radiometer and the powerful resources of the Yerkes Observatory E. F. Nichols succeeded in 1898 and 1900 in obtaining indications of heat from Arcturus and Vega, as well as from Jupiter and Saturn (*Astrophysical Journ.* xiii. 101), the heat received being comparable with that from a candle 6 m. away. We may place alongside this result that obtained by W. J. Dibdin (*Proc. Roy. Soc.*, April 1892), who compared candle-light with twenty-one stars ranging to the sixth magnitude, and found the light of a second magnitude star equal to that of a candle at 1260 ft. (H. H. T.)

Very little Heat from the Stars.

PHRAATES (Phrahates; Pers. *Frahāt*, modern *Ferhāt*), the name of five Parthian kings.

1. Phraates I., son of Priapatius, reigned *c.* 175–170 B.C. He subdued the Mardi, a mountainous tribe in the Elburz (Justin xli. 5; Isid. Charac. 7). He died young, and appointed as his successor not one of his sons, but his brother Mithradates I. (Justin xli. 5).

2. Phraates II., son of Mithradates I., the conqueror of Babylonia, reigned 138–127. He was attacked in 130 by Antiochus VII. Sidetes, who, however, in 129 was defeated and killed in a great battle in Media, which ended the Seleucid rule east of the Euphrates (see Seleucid Dynasty). Meanwhile the kingdom was invaded by the Scythians (the Tochari of Bactria), who had helped Antiochus. Phraates marched against them, but was defeated and killed (Justin xlii. 1; Johannes Antioch, *fr.* 66).

3. Phraates III., "the God" (Phlegon, *fr.* 12 *ap.* Photius *cod.* 97 and on some of his coins), succeeded his father, Sanatruces, in 70 B.C., at the time when Lucullus was preparing to attack Tigranes of Armenia, who was supreme in western Asia and had wrested Mesopotamia and several vassal states from the Parthian kingdom. Naturally, Phraates declined to assist Mithradates of Pontus and Tigranes against the Romans (see Tigranes). He supported his son-in-law, the younger Tigranes, when he rebelled against his father, and invaded Armenia (65 B.C.) in alliance with Pompey, who abandoned Mesopotamia to the Parthians (Dio. Cass. xxxvi. 45, 51; Appian, *Mithr.* 104; Liv. *Epit.* 100). But Pompey soon overrode the treaty; he acknowledged the elder Tigranes, took his son prisoner, occupied the vassal states Gordyene and Osroëne for the Romans, and denied the title of "king of kings," which Phraates had adopted again, to the Parthian king (Plut. *Pomp.* 33, 38; Dio. Cass. xxxvii. 5 seq.). About 57 Phraates was murdered by his two sons, Orodes I. and Mithradates III.

4. Phraates IV., son of Orodes I., by whom he was appointed successor in 37 B.C., after the death of Pacorus. He soon murdered his father and all his thirty brothers (Justin xlii. 5; Plut. *Crass.* 33; Dio Cass. xlix. 23). He was attacked in 36 by Antonius (Mark Antony), who marched through Armenia into Media Atropatene, and was defeated and lost the greater part of his army. Believing himself betrayed by Artavasdes, king of Armenia, he invaded his kingdom in 34, took him prisoner, and concluded a treaty with another Artavasdes, king of Atropatene. But when the war with Octavianus Augustus broke out, he could not maintain his conquests; Phraates recovered Atropatene and drove Artaxes, the son of Artavasdes, back into Armenia (Dio. Cass. xlix. 24 sqq., 39 seq., 44; cf. li. 16; Plut. *Antonius*, 37 seq.). But by his many cruelties Phraates had roused the indignation of his subjects, who raised Tiridates II. to the throne in 32. Phraates was restored by the Scythians, and Tiridates fled into Syria. The Romans hoped that Augustus would avenge the defeat of Crassus on the Parthians, but he contented himself with a treaty, by which Phraates gave back the prisoners and the conquered eagles (20 B.C., *Mon. Anc.* 5, 40 sqq.; Justin xlii. 5); the kingdom of Armenia also was recognized as a Roman dependency. Soon afterwards Phraates, whose greatest enemies were his own family, sent five of his sons as hostages to Augustus, thus acknowledging his dependence on Rome. This plan he adopted on the advice of an Italian concubine whom he made his legitimate wife under the name of "the goddess Musa"; her son Phraates, commonly called Phraataces (a diminutive form), he appointed successor. About 4 B.C. he was murdered by Musa and her son (Joseph. *Ant.* xviii. 2, 4).

5. Phraates V., or Phraataces, the younger son of Phraates IV. and the "goddess Musa," with whom he is associated on his coins. Under him a war threatened to break out with Rome about the supremacy in Armenia and Media. But when Augustus sent his adopted son Gaius Caesar into the east in order to invade Parthia, the Parthians preferred to conclude a

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

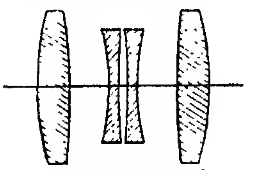

FIG. 53.—Beck-Steinheil "Unofocal."

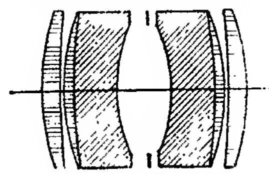

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°–65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

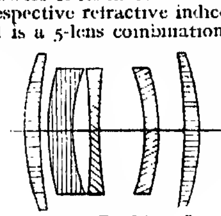

FIG. 55.—Beck's "Isostigmar."

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Porro and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Telediopiricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

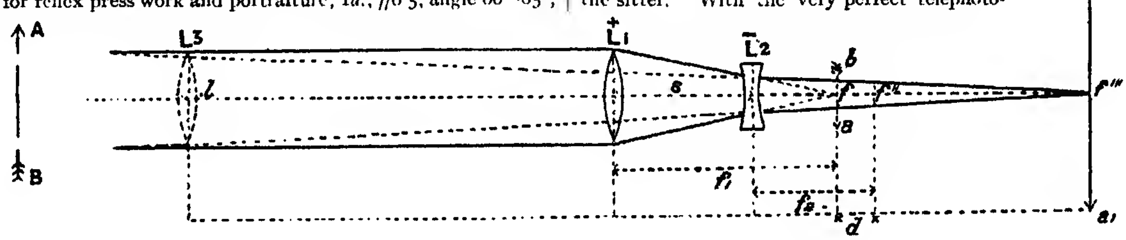

FIG. 56.

their writings to the relation of soul to body naturally adopted the teaching of Galen which they accommodated to their theology, thereby conferring on it an importance which rendered correction difficult. Tertullian [1] in a sense expresses his belief in a theory of localization as also at a later period does Thomas Aquinas.[2]

Early in the 13th century Albertus Magnus [3] gave a detailed description of the distribution of mental and psychical faculties in the head. The anterior region he assigned to judgment, the middle to imagination, and the posterior to memory. A somewhat similar allocation was made by Gordon, professor of medicine in Montpellier (1296),[4] who assigned common sensation and the reception of impressions to the anterior cornua of the lateral ventricles, *phantasia* to the posterior, this power being twofold (*imaginativa* and *cogitativa*), judgment or *aestimativa* to the third ventricle, and memory to the fourth.[5] Figures of a similar division were given by Petrus Montagnana [6] and Lodovico Dolce [7] still later by Ghiradelli of Bologna [8] and by Theodore Gall of Antwerp.[9] That the "vital spirits" resided in the ventricles was doubted by many, and denied by a few of the anatomists of the 17th century. G. Bauhin in 1621 [10] attacked the old view, and Hoffmann of Altorf showed that, as the ventricles were closed cavities, they could not transmit any material fluid. That these spirits existed at all was doubted by Alexander Benedictus,[11] Plater,[12] and a few others; but they were believed in by the great majority of 17th and even of 18th century medical writers, many of whom conceived that the ventricles were *semper pleni spiritibus animalibus flammulis similibus, quorum beneficiis intelligimus, sentimus, et movemus*,[13] and the opponents of this view were strongly assailed by J. Riolan and others as revolutionary. Columbus [14] ridiculed the idea that the convoluted surface can have anything to do with intellect, as the ass, a proverbially stupid animal, has a convoluted cerebrum. According to his view, the convolutions are for the purpose of lightening the brain and facilitating its movements. The grey matter of the surface of the cerebrum was recognized as the true dynamic element by M. Malpighi [15] and T. Willis.[16] The latter regarded the convoluted surface of the cerebrum as the seat of the memory and the will, the convolutions being intended to retain the animal spirits for the various acts of imagination and memory. Imagination he described as seated in the corpus callosum, sense-perception in the corpus striatum, and *impetus et perturbatio* in the basal parts of the cerebrum above the crura. The thalami he regarded as the centres of sight and the cerebellum of involuntary acts. Succeeding anatomists simply varied these localizations according to their respective fancies. G. M. Lancisi placed sense-perception in the corpus callosum, R. Vieussens in the centrum ovale majus. R. Descartes supposed the soul to be seated in the pineal gland, others in the brain-commissures especially the pons Varolii.[17] Meyer considered abstract ideas to arise in the cerebellum, and memory to have its seat at the roots of the nerves.[18]

Of later writers three deserve special notice, as having largely prepared the way for the more modern school of phrenology. J. A. Unzer, of Halle, in his work on physiology extended the pre-existing theories of localization. Metzger,[19] twenty years before the publication of Prochaska's work, had proposed to make a series of observations on the anatomical characters of the brains of persons of marked intellectual peculiarity; but apparently he did not carry this into effect. In a more special manner Prochaska of Vienna may be looked upon as the father of phrenology, as in his work on the nervous system, published in Vienna in 1784, are to be found the germs of the later views which were propounded in that city twelve years later.[20]

The system formulated by Gall (*q.v.*) is thus a modern expansion of an old empirical philosophy, and its immediate parentage is easily traced, although, according to Gall's account, it was with him the result of independent observations. These, he tells us, he began to make at an early age, by learning to correlate the outward appearances and mental qualities of his school-fellows. Gall's first published paper was a letter in the *Deutscher Merkur* of December 1798, but his principal expositions were oral, and attracted much popular attention, which increased when, in 1802, he was commanded by the Austrian government, at the instance of the ecclesiastical authorities, to discontinue his public lectures. In 1804 he obtained the co-operation of Spurzheim (1776–1832), a native of Longwich, near Treves, who became his pupil in 1800, and proved a powerful ally in promulgating the system. Master and pupil at first taught in harmony, but they found it advisable to separate in 1813; and we find Spurzheim, several years after their parting, declaring that Gall had not introduced any improvements into his system since their separation (notes to Chenevix, p. 99). "My philosophical views," he also says, "widely differ from those of Gall."

In Paris, where he settled in 1807, Gall made many influential converts to his system. F. J. V. Broussais, H. M. D. de Blainville, H. Cloquet, G. Andral, E. Geoffroy St-Hilaire, Vimont and others adopted it and countenanced its progress. Gall visited Great Britain, but the diffusion of phrenology here was chiefly due to Spurzheim, who lectured through the country and through America, and with the aid of his pupil, George Combe, attracted a large popular following. His most influential disciples were J. Elliotson, Andrew Combe, Sir G. S. Mackenzie, R. Macnish, T. Laycock and Archbishop R. Whately, and in America Caldwell and J. Godman. On the opposite side many influential men took up a strongly antagonistic position, prominent among whom were J. Barclay the anatomist, P. M. Roget, Sir Charles Bell, Sir W. Hamilton, F. Jeffrey, H. P. Brougham, T. Brown and Sir B. Brodie. The nature of the system rendered it eminently fitted to catch public attention, and it rapidly attained to so great a

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), $f/6$, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), $f/4{\cdot}5$ is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of $f/4{\cdot}5$ can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., $f/4{\cdot}5$, for portraiture, rapid hand-camera work, telephotography and projection; and I., $f/6$, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

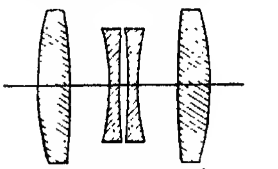

FIG. 53.—Beck-Steinheil "Unofocal."

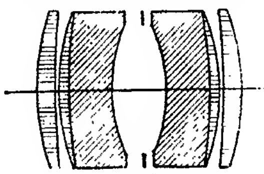

FIG. 54.—Euryplan, $f/4{\cdot}5$.

wide angle, made in four series: I., $f/4{\cdot}5$, angle 80°; II., $f/5{\cdot}6$, angle 90°; III., $f/6{\cdot}8$ to $7{\cdot}5$, angle 82°; IV., $f/6{\cdot}5$. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., $f/4{\cdot}5$, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), $f/4{\cdot}5$, large aperture, series, for reflex press work and portraiture; I*a*., $f/6{\cdot}5$, angle 60°–65°, long focus, for portraiture, &c.; II., $f/5{\cdot}8$, angle 70°, for general use, III. $f/7{\cdot}7$, angle 65°, similar to II. but less rapid; IV. $f/6{\cdot}3$, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

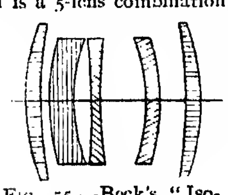

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), $f/11$, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), $f/5{\cdot}6$, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1860 by MM. Porro and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Telediotpricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

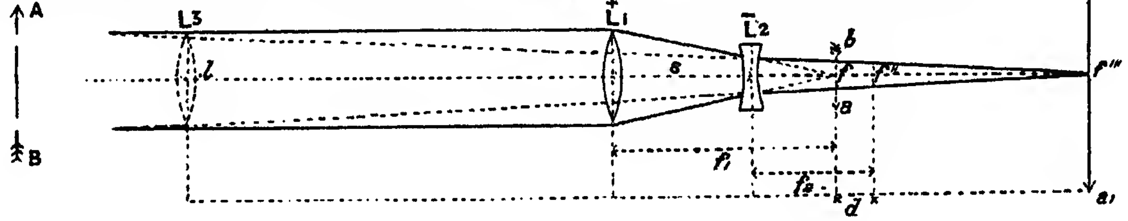

FIG. 56.

Superior Sentiments.

13. Benevolence (*Bonté*), on the middle of the frontal bone in front of the coronal suture; here Gall noticed a rising on the head of the highly commended servant of a friend, as well as on a benevolent schoolmate who nursed his brothers and sisters when they were ill. To this spot Xenocrates referred the intellectual powers.

14. Veneration (*Sentiment réligieux*), median at the bregma. Gall noted when visiting churches that those who prayed with the greatest fervour were prominent in this region, and it was also prominent in a pious brother.

15. Conscientiousness, Believingness (Forster), unknown to Gall; recognized by Spurzheim usually from its deficiency, and placed between the last and the parietal eminence.

16. Firmness (*Fermeté*), median, on the sagittal suture from behind the bregma to the front of the obelion. Lavater first pointed out that persons of determination had lofty heads.

17. Hope, not regarded as primary by Gall, who believed hope to be akin to desire and a function of every faculty which desires and left this territory unallocated.

18. Wonder, said to be large in vision-seers and many psychic researchers. A second similar organ placed between this and the next is called Mysterizingness by Forster, and is said to be the seat of belief in ghosts and in the supernatural.

19. Ideality (*Poésie*), noted by Gall from its prominence in the busts of poets; said to be the part touched by the hand when composing poetry.

20. Wit (*Esprit caustique*), the frontal eminence, the organ of the sense of the ludicrous, prominent in F. Rabelais and J. Swift.

21. Imitation (*Faculté d'imiter*), disposition to mimicry, placed between Benevolence and Wonder.

Perceptive Faculties.

22. Individuality, over the frontal sinus in the middle line; the capacity of recognizing external objects and forming ideas therefrom; said to have been large in Michelangelo, and small in the Scots.

23. Form (*Mémoire des personnes*), capacity of recognizing faces; gives a wide interval between the eyes; found by Gall in a squinting girl with a good memory for faces.

24. Size, over the trochlea at the orbital edge; described by Spurzheim and Vimont as the capacity of estimating space and distance.

25. Weight, outside the last on the orbital edge and, like it, over the frontal sinus. The prominence of ridge here is due to large sinus or a projecting bone. Certain old writers, such as Strato Physicus, located the whole intellect in this ridge.

26. Colour, also on the orbital edge external to the last.

27. Locality (*Sens de localité*), placed above Individuality on each side, and corresponding to the upper part of the frontal sinus and to the region immediately above it.

28. Number, on the external angular process of the frontal bone, large in a calculating boy in Vienna.

29. Order, internal to the last, first noted by Spurzheim in an orderly idiot.

30. Eventuality (*Mémoire des choses*), the median projection above the glabella, supposed to be the seat of the memory of events.

31. Time, below the frontal eminence and a little in front of the temporal crest.

32. Tune (*Sens des rapports des tons*), on the foremost part of the temporal muscle, where Gall noticed a bulge on the head of a musical prodigy of five.

33. Language (*Sens des mots*), behind the eye. This was the first organ noticed by Gall, as a clever schoolfellow, quick at languages, had prominent eyes. Old authors had noted the connexion between prominent eyeballs and mental development; thus Gazzali and Syenensis Medicus Cyprius place the intellect and soul behind the eyeballs.

Reflective Faculties.

34. Comparison (*Sagacité comparative*), median, at the top of the bare region of the forehead, where a savant friend of Gall's, fond of analogies, had a prominent boss.

35. Causality (*Esprit métaphysique*), the eminence on each side of Comparison, noticed on the head of Fichte and on a bust of Kant; the seat of the faculty of correlating causes and effects.

The first identification of each organ was made by an induction from very limited data, but the founders and exponents of the system have collected all available instances wherein enlargements of each of these regions coexisted with increased powers of the faculty supposed to reside therein, and in some cases they have discovered coincidences of a surprising nature. When, however, such do not exist, a convenient excuse is found by reference to the indefinite article of temperament, or by a supposed explanation of the faculty in question as not simple but produced by the co-operation of other influences. Thus, as Sheridan's bump of wit was small, he is said not to have been truly witty; but to have had comparison and memory strongly developed. The girl Labrosse (described in Férussac's *Bulletin* for October 1831), who exhibited strong amativeness but had a rudimentary cerebellum, is said to have obliterated it by over-use. Thurtell, a cold-blooded murderer, whose organ of benevolence was large, is said to have been generous, as he once gave half-a-guinea to a friend, &c.

The method whereby the sizes of organs are estimated is arbitrary and the boundaries of the regions indefinite. The attempts of Nicol, Straton and Wight to devise mechanical and accurate modes of measurement have not been very successful and have not found favour with the professional phrenologist.

Anatomical Aspect of Phrenology.—The phrenological controversy served the useful purpose of stimulating research into the anatomy of the brain; but we owe very little of solid progress to the advocates of the system. Gall is the only writer of his creed in whose works original observations of value are to be found, and Dr B. Holländer has cited many interesting and carefully recorded anatomical and clinical facts in his writings. Although the study of the surface of the cerebrum is of the essence of phrenology, yet nowhere in the circle of phrenological literature are the convolutions of the brain accurately described; our knowledge of their order and disposition comes from the morphologist, not from the phrenologist. The first real step towards their systematic description was made by L. Rolando,[1] who in 1830 described the fissure to which his name is attached, and very little advance was made until the publication in 1856 of L. P. Gratiolet's [2] and Huschke's [3] memoirs. These works for the first time placed the description of the surface of the brain, imperfectly attempted by L. A. Desmoulins in 1825,[4] on a satisfactory basis.

A description of the anatomy of the brain is given under the heading BRAIN, so it is necessary here only to refer to points not included in that account.

1. Any psychological theory which correlates brain-action and mental phenomena requires a correspondence between brain-size and mental power; and, speaking generally, the brains of those whose capacities are above the average are larger than those of the general run of their fellow-men.

2. Direct measurements of the relative developments of different portions of brains are difficult and troublesome to make; but their importance to phrenologists is so great that it is remarkable that no attempts to obtain any such were made by them. The series given by R. Wagner of the relative sizes of the cerebral lobes of four brains is almost the only record of importance in this direction, and is appended.

Brain of	Square Inches. Surface of Frontal Lobe.	Surface of Parietal Lobe.	Surface of Occipital Lobe.	Surface of Temporo-Sphenoidal.	Relation of Frontal Lobe (Perceptive and Reflective Organs) to whole Surface = 1.	Relation of Parietal Lobe (Sentiments) to Surface = 1.	Relation of Remaining Surface (Propensities) to Surface = 1.	Extent of Free Surface.	Extent of Surface of Involutions.	Total Extent of Surface.	Weight in Grammes.
Fuchs, clinical teacher . .	143·4	69·5	59	67·5	·419	·203	·340	110·7	231·3	342	1499
Gauss, mathematician . .	139	70·6	59·4	68·4	·407	·207	·374	112·8	228·2	341	1492
Workman . .	113·2	62·3	50·3	62	·385	·214	·385	97·4	193·6	291	1273
Woman . . .	130	65	51	66·8	·409	·204	·370	107·5	209·9	317·4	1185

From this it appears that the woman exceeded Gauss in perceptive and reflective organs, exceeded Fuchs in sentiment, and fell below the workman in propensities. It must be said, however, that the phrenological divisions do not accurately coincide with the anatomical. It would furnish important physiological data if the brains of men distinguished for special qualities were examined in this or some comparable way.

3. It is important in relation to phrenology to ascertain the constancy of the convolutions. Many varieties in the detail of the surface-patterns have been recorded by Tenchini, Poggi, Giacomini, N. Rüdinger, Cunningham and Sernow,[5] but the general plan is fairly uniform. A still more important question has been recently raised by J. N. Langley, viz. how far identical spots on

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°–65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

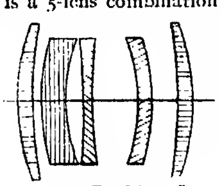

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Bonie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice*, *Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

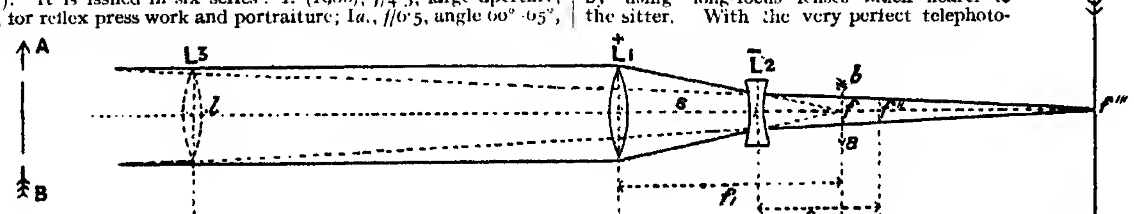

FIG. 56.

and higher-lying grey portions of the nervous centres there is an a priori presumption in favour of the extension of this principle of localization. This has been premised on metaphysical as well as on anatomical grounds. A. B. Bonnet long ago believed each portion of the brain to have a specifically separate function, and Herbert Spencer has said that "no physiologist can long resist the conviction that different parts of the cerebrum subserve different kinds of mental action. Localization of function is the law of all organization; separateness of duty is universally accompanied with separateness of structure, and it would be marvellous were an exception to exist in the cerebral hemispheres. Let it be granted that the cerebral hemispheres are the seats of the higher psychical activities; let it be granted that among these higher psychical activities there are distinctions of kind which, though not definite, are yet practically recognizable, and it cannot be denied, without going in direct opposition to established physiological principles, that these more or less distinct kinds of psychical activity must be carried on in more or less distinct parts of the cerebral hemisphere."

For a masterly review of the old and the new association and localization theories, see W. Wundt's *Grundzüge der physiologischen Psychologie*, i. 289 sqq.; also the same author's *Essays* (Leipzig, 1888), pp. 109 sqq.

There is a large weight of evidence in favour of the existence of some form of localization of function. So little is known of the physical changes which underlie psychical phenomena, or indeed of the succession of the psychical processes themselves, that we cannot as yet judge as to the nature of the mechanism of these centres. So much of the psychic work of the individual life consists in the interpretation of sensations and the translation of these into motions that there are strong a priori grounds for expecting to find that much of the material of the nerve-centres is occupied with this kind of work, but in the present conflict of experimental evidence it is safer to suspend judgment. That these local areas are not centres in the sense of being indispensable parts of their respective motor apparatus is clear, as the function abolished by ablation of a part returns, though tardily, so that whatever superintendence the removed region exercised apparently becomes assumed by another part of the brain.[1] Experimental physiology and pathology, by suggesting other functions for parts of the brain-surface, are thus directly subversive of many details of the phrenology of Gall and Spurzheim.

Psychological Aspect.—The fundamental hypothesis which underlies phrenology as a system of mental science is that mental phenomena are resolvable into the manifestations of a group of separate faculties. A faculty is defined as "a convenient expression for the particular states into which the mind enters when influenced by particular organs; it is applied to the feelings as well as to the intellect, thus the faculty of benevolence means every mode of benevolence induced by the organ of benevolence" (Combe). In another work the same author says it is "used to denote a particular power of feeling, thinking, perceiving, connected with a particular part of the brain." The assumption is contained in the definition that the exercise of a faculty is the physical outcome of the activity of the organ, and in several of the standard works this is illustrated by misleading analogies between these and other organs; thus the organs of benevolence and of firmness are said to be as distinct as the liver and pancreas. The mind, according to another author, consists of the sum of all the faculties. In this view the unity of consciousness is somewhat difficult to explain, and consequently there is assumed by others a single unifying substratum, and on this the organs are supposed to act; thus thoughts are defined as "relations of the simple substance, mind, to certain portions of the encephalon" (Welsh, *Phren. Journ.* i. 206). Gall himself believed that there was but a single principle which saw, felt, tasted, heard, touched, thought and willed (*Fonctions du cerveau*, i. 243); and the American exponent of phrenology, Caldwell, says "the mind is as single in its power as it is in its substance; it is a quickening and operating principle, essential to all the mental faculties, but does not, by any means, possess them itself" (*Elements*, p. 16). It is not easy to understand the supposed relation of this hypothetical substratum to the separate faculties acting on it. It must be both immaterial and unconnected with the brain, as the whole two thousand million cells supposed to exist in the cerebral hemispheres are all parcelled out among the faculties, and none are left for the unifying *nous*.

Each organ is considered as engaged, either independently in bringing forth its own product, or collectively with others in elaborating compound mental states, and according to their several degrees of development and activity they are considered capable of perceiving, conceiving, recollecting, judging or imagining each its own subject. This mechanical conception of the division of labour in the production of the phenomena of mind has the charm of simplicity, but is attended with the difficulty that arises in discriminating the operations of the different organs one from the other. Phrenologists are apt to be vague respecting the limits of the several faculties, as about the boundaries of the separate organs. It was pointed out by Jeffrey that the lines of demarcation between benevolence, adhesiveness and philoprogenitiveness were indeterminate, although the organs are not very close, and the same applies to other organs.

It is unfortunate for the clearness of the definition that, although historically the faculties were the first phenomena noted, independent of and previous to their localization, yet in the definition the faculties are defined in terms of their localities.

The following arguments are adduced in favour of the fundamental separateness of the faculties: (1) analogy—elsewhere in the animal economy division of labour is the rule; (2) the variety of mental endowment observed among children before they are influenced by education, and the inequalities in the mental endowments of individuals; (3) the phenomena of insanity, especially of monomania; (4) the varying periods at which individual faculties attain their maximum development; (5) the phenomena of dreams, and the awakening of a limited number of faculties during them; (6) pain being felt in an organ when it is overtaxed.[2]

Such faculties are supposed to be primary—(1) as exist in some animals and not in others, (2) as vary in their development in the sexes, (3) as are developed in varying proportions with regard to other faculties, (4) as may act separately from other faculties, (5) as are not necessarily simultaneous with other faculties in action, (6) as are hereditary, and (7) as may be singly diseased.

According to the development of their powers mankind may be divided into six classes: (1) those in whom the highest qualities are largely developed and the animal qualities feeble; (2) those with the reversed conditions developed, with large animal and feeble intellectual and moral faculties; (3) those in whom good and evil are in constant war, with active animal and strong intellectual faculties and sentiments; (4) those partial geniuses in whom a few qualities are unusually developed, while the rest are at or below the mediocre standard; (5) those men of moderate endowment in whom some faculties are nearly or quite deficient; (6) those with an unvarying standard of undistinguished mediocrity in all their faculties.

It is perhaps unfortunate that the word "faculty" has been used in this sense of original power by phrenologists. It would have been better to employ, as Mr Lewes suggests, the term

[1] For cases, see Rochefontaine, *Archives de Physiologie* (1883), 28; Bianchi, *La Psichiatria*, i. 97.

[2] It is interesting in this connexion to note that in a case published by Professor Hamilton in *Brain* (April 1884), where a tumour existed on the occipital lobe, the pain was persistently referred to the forehead. Many similar cases are to be noticed among the records of localized brain-lesions. Bearing on this point also it is worth noting, once for all, that in nothing is the purely hypothetical nature of phrenological description better realized than in the accounts of what these authors call the "natural language of the faculties,"—that poets are supposed to touch ideality when composing, musicians to press on tone and time, and painters on form and colour, when in the exercise of their arts! Yet we are gravely taught this in the standard works on the subject.

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=O$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°,

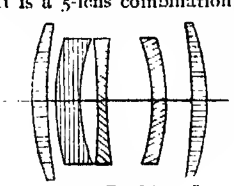

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Bonie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephoto-

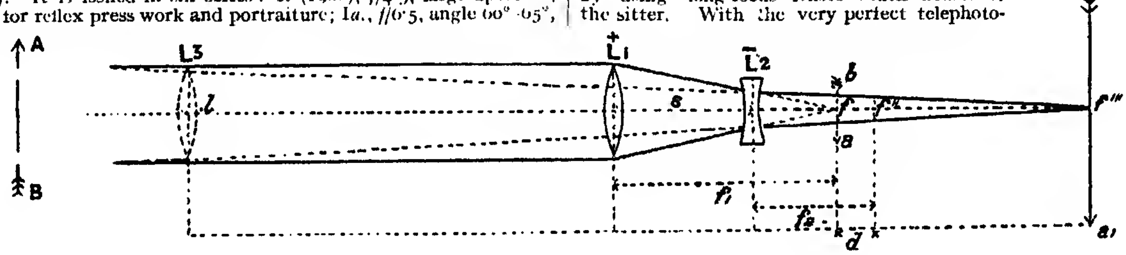

FIG. 56.

long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

graphic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

complete success, till some time between 610 and 590. Phrygia then fell under the Lydian power, and by the treaty of 585 the Halys was definitely fixed as the boundary between Lydia and Media (see Lydia and Persia). The period from 675 to 585 must therefore be considered as one of great disturbance and probably of complete paralysis in Phrygia. After 585 the country was ruled again by its own princes under subjection to Lydian supremacy. To judge from the monuments, it appears to have recovered some of its old prosperity; but the art of this later period has to a great extent lost the strongly marked individuality of its earlier bloom. The later sepulchral monuments belong to a class which is widely spread over Asia Minor from Lycia to Pontus. The graves are made inside a chamber excavated in the rock, and the front of the chamber imitates a house or temple. No attempt is made to conceal the entrance or to render it inaccessible. The architectural details are in some cases unmistakably copied, without intentional modification, from the architecture of Greek temples; others point perhaps to Persian influence, while several—which are perhaps among the early works of this period—show the old freedom and power of employing in new and original ways details partly learned from abroad. This style continued in use under the Persians, under whose rule the Phrygians passed when Cyrus defeated Croesus in 546, and lasted till the Roman period. One monument appears to presuppose a development of Greek plastic art later than the time of Alexander[1] and is almost certainly of the Roman time. It would, however, be wrong to suppose that the influence of truly Hellenic art on Phrygia began with the conquest of Alexander. Under the later Mermnad kings the Lydian empire was penetrated with Greek influence, and Xanthus, the early Lydian historian, wrote his history in Greek. Under the Persian rule perhaps it was more difficult for Greek manners to spread far east; but we need not think that European influence was absolutely unfelt even in Phrygia. The probability is that Alexander found in all the large cities a party favourable to Greek manners and trade. Very little is to be learned from the ancient writers with regard to the state of Phrygia from 585 to 300. The slave-trade flourished: Phrygian slaves were common in the Greek market, and the Phrygian names Midas and Manes were stock-names for slaves. Herodotus (i. 14) records that a king Midas of Phrygia dedicated his own chair at Delphi; the chair stood in the treasury of Cypselus, and cannot have been deposited there before 680 to 660 B.C. It is not improbable that the event belongs to the time of Alyattes or Croesus, when Greek influence was favoured throughout the Lydian empire; and it is easy to understand how the offering of a king Midas should be considered, in the time of Herodotus, as the earliest made by a foreign prince to a Greek god. The Phrygian troops in the army of Xerxes were armed like the Armenians and led by the same commander.

It is to be presumed that the cities of the Sangarius valley gradually lost importance in the Persian period. The final catastrophe was the invasion of the Gauls about 270 to 250; and, though the circumstances of this invasion are almost unknown, yet we may safely reckon among them the complete devastation of northern Phrygia. At last Attalus I. settled the Gauls permanently in eastern Phrygia, and a large part of the country was henceforth known as Galatia. Strabo mentions that the great cities of ancient Phrygia were in his time either deserted or marked by mere villages. The great city over the tomb of Midas has remained uninhabited down to the present day. About 5 m. west of it, near the modern Kumbet, stood Metropolis, a bishopric in the Byzantine time, but never mentioned under the Roman empire.

Alexander the Great placed Phrygia under the command of Antigonus, who retained it when the empire was broken up. When Antigonus was defeated and slain, at the decisive battle of Ipsus, Phrygia came under the sway of Seleucus. As the Pergamenian kings grew powerful, and at last confined the Gauls in eastern Phrygia, the western half of the country was incorporated in the kingdom of Pergamum. Under the Roman empire Phrygia had no political existence under a separate government, but formed part of the vast province of Asia. In autumn 85 B.C. the pacification of the province was completed by Sulla, and throughout the imperial time it was common for the Phrygians to date from this era. The imperial rule was highly favourable to the spread of Hellenistic civilization, which under the Greek kings had affected only a few of the great cities, leaving the mass of the country purely Phrygian. A good deal of local self-government was permitted; the cities struck their own bronze coins, inscribed on them the names of their own magistrates,[2] and probably administered their own laws in matters purely local. The western part of the country was pervaded by Graeco-Roman civilization very much sooner than the central, and in the country districts the Phrygian language[3] continued in common use at least as late as the third century after Christ.

When the Roman empire was reorganized by Diocletian at the end of the 3rd century Phrygia was divided into two provinces, distinguished at first as Prima and Secunda, or Great and Little, for which the names Pacatiana and Salutaris soon came into general use. Pacatiana comprised the western half, which had long been completely pervaded by Graeco-Roman manners, and Salutaris the eastern, in which the native manners and language were still not extinct. Each province was governed by a *praeses* or ἡγεμών about A.D. 412, but shortly after this date an officer of consular rank was sent to each province (Hierocles, *Synecd.*). About 535 Justinian made some changes in the provincial administration: the governor of Pacatiana was henceforth a *comes*, while Salutaris was still ruled by a *consularis*. When the provinces of the Eastern empire were reorganized and divided into *themata* the two Phrygias were broken up between the Anatolic, Opsician and Thracesian themes, and the name Phrygia finally disappeared. Almost the whole of Byzantine Phrygia is now included in the vilayet of Brusa, with the exception of a small part of Parorius and the district about Themisonium (Karayuk Bazar) and Ceretapa (Kayadibi), which belong to the vilayet of Konia, and the district of Laodicea and Hierapolis, which belongs to Aidin. The principal modern cities are Kutaiah (Cotyaeum), Eski Shehir (Dorylaeum), Afiom Kara Hissar (near Prymnessus), and Ushak (Trajanopolis).

It is impossible to say anything definite about the boundaries of Phrygia before the 5th century. Under the Persians Great Phrygia extended on the east to the Halys and the Salt Desert; Xenophon (*Anab.* i. 2, 19) includes Iconium on the south-east within the province, whereas Strabo makes Tyriaeum the boundary in this direction. The southern frontier is unknown: the language of Livy (xxxviii. 15) implies that the southern Metropolis (in the Tchul Ova) belonged to Pisidia; but Strabo (p. 629) includes it in Phrygia. Celaenae, beside the later city of Apamea (Dineir), and the entire valley of the Lycus, were Phrygian. The Maeander above its junction with the Lycus formed for a little way the boundary between Phrygia and Lydia. The great plateau now called the Banaz Ova was entirely or in great part Phrygian. Mt Dindymus (Murad Dagh) marked the frontier of Mysia, and the entire valley of the Tembrogius or Tembris (Porsuk Su) was certainly included in Phrygia. The boundaries of the two Byzantine Phrygias were not always the same.

Taking Hierocles as authority, the extent of the two provinces at the beginning of the 6th century will be readily gathered from the accompanying list, in which those towns which coined money under the Roman empire are italicized and the name of the nearest modern village is appended.

I. Pacatina.—(1) *Laodicea* (Eski Hissar); (2) *Hierapolis* (Pambuk Kalessi); (3) Mosyna (Geveze); (4) Motellopolis, only in *Notitiae*

[1] A gorgoneum of Roman period, on a tomb engraved in *Journ. Hell. Stud.* (Pl. xxvi.).

[2] This liberty was not granted to the cities of any other province in Anatolia.

[3] A number of inscriptions in a language presumably Phrygian have been discovered in the centre and east of the country; they belong generally to the end of the 2nd and to the 3rd century.

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

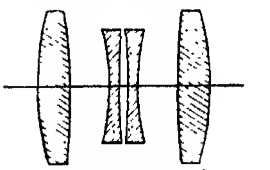

Fig. 53.—Beck-Steinheil "Unofocal."

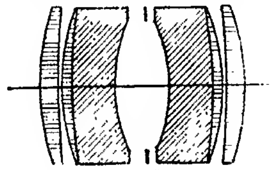

Fig. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f) = 0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°–65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

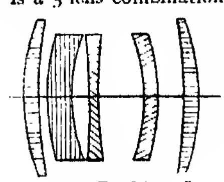

Fig. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Bonie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Telediopticus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

PHRYNE, Greek courtesan, lived in the 4th century B.C. Her real name was Mnesarete, but owing to her complexion she was called Phryne (toad), a name given to other courtesans. She was born at Thespiae in Boeotia, but seems to have lived at Athens. She acquired so much wealth by her extraordinary beauty that she offered to rebuild the walls of Thebes, which had been destroyed by Alexander the Great (336), on condition that the words "Destroyed by Alexander, restored by Phryne the courtesan," were inscribed upon them. On the occasion of a festival of Poseidon at Eleusis she laid aside her garments, let down her hair, and stepped into the sea in the sight of the people, thus suggesting to the painter Apelles his great picture of Aphrodite Anadyomene, for which Phryne sat as model. She was also (according to some) the model for the statue of the Cnidian Aphrodite by Praxiteles. When accused of profaning the Eleusinian mysteries, she was defended by the orator Hypereides, one of her lovers. When it seemed as if the verdict would be unfavourable, he rent her robe and displayed her lovely bosom, which so moved her judges that they acquitted her. According to others, she herself thus displayed her charms. She is said to have made an attempt on the virtue of the philosopher Xenocrates. A statue of Phryne, the work of Praxiteles, was placed in a temple at Thespiae by the side of a statue of Aphrodite by the same artist.

See Athenaeus, pp. 558, 567, 583, 585, 590, 591; Aelian, *Var. Hist.* ix. 32; Pliny, *Nat. Hist.* xxxiv. 71.

PHRYNICHUS. 1. Son of Polyphradmon and pupil of Thespis, one of the earliest of the Greek tragedians. Some of the ancients, indeed, regarded him as the real founder of tragedy. He gained his first poetical victory in 511 B.C. His famous play, the *Capture of Miletus*, was probably composed shortly after the conquest of that city by the Persians. The audience was moved to tears, the poet was fined for reminding the Athenians of their misfortunes, and it was decreed that no play on the subject should be produced again. In 476 Phrynichus was successful with the *Phoenissae*, so called from the Phoenician women who formed the chorus, which celebrated the defeat of Xerxes at Salamis (480). Themistocles acted as choragus, and one of the objects of the play was to remind the Athenians of his great deeds. The *Persians* of Aeschylus (472) was an imitation of the *Phoenissae*. Phrynichus is said to have died in Sicily. Some of the titles of his plays, *Danaïdes, Actaeon, Alcestis, Tantalus*, show that he treated mythological as well as contemporary subjects. He introduced a separate actor as distinct from the leader of the chorus, and thus laid the foundation of dialogue. But in his plays, as in the early tragedies generally, the dramatic element was subordinate to the lyric element as represented by the chorus and the dance. According to Suidas, Phrynichus first introduced female characters on the stage (played by men in masks), and made special use of the trochaic tetrameter.

Fragments in A. Nauck, *Tragicorum graecorum fragmenta* (1887).

2. A poet of the Old Attic comedy and a contemporary of Aristophanes. His first comedy was exhibited in 429 B.C. He composed ten plays, of which the *Solitary* (Μονότροπος) was exhibited in 414 along with the *Birds* of Aristophanes and gained the third prize. The *Muses* carried off the second prize in 405, Aristophanes being first with the *Frogs*, in which he accuses Phrynichus of employing vulgar tricks to raise a laugh, of plagiarism and bad versification.

Fragments in T. Kock, *Comicorum atticorum fragmenta* (1880).

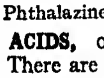
3. Phrynichus Arabius, a grammarian of Bithynia, lived in the 2nd century A.D. According to Suïdas he was the author of (1) an *Atticist*, or *On Attic Words*, in two books; (2) *Τιθεμένων συναγωγή*, a collection of subjects for discussion; (3) *Σοφιστικὴ παρασκευή*, or Sophistical Equipment, in forty-seven (or seventy-four) books. As models of Attic style Phrynichus assigned the highest place to Plato, Demosthenes and Aeschines the Socratic. The work was learned, but prolix and garrulous. A fragment contained in a Paris MS. was published by B. de Montfaucon, and by I. Bekker in his *Anecdota graeca* (1814). Another work of Phrynichus, not mentioned by Photius, but perhaps identical with the *Atticist* mentioned by Suïdas, the *Selection* (Ἐκλογή) *of Attic Words and Phrases*, is extant. It is dedicated to Cornelianus, a man of literary tastes, and one of the imperial secretaries, who had invited the author to undertake the work. It is a collection of current words and forms which deviated from the Old Attic standard, the true Attic equivalents being given side by side. The work is thus a lexicon anti-barbarum, and is interesting as illustrating the changes through which the Greek language had passed between the 4th century B.C. and the 2nd century A.D.

Editions of the Ἐκλογή, with valuable notes, have been published by C. A. Lobeck (1820) and W. G. Rutherford (1881); Lobeck devotes his attention chiefly to the later, Rutherford to the earlier usages noticed by Phrynichus. See also J. Brenous, *De Phrynicho Atticista* (1895).

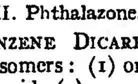
4. An Athenian general in the Peloponnesian War. He took a leading part in establishing the oligarchy of the Four Hundred at Athens in 411 B.C., and was assassinated in the same year (Thucydides viii.).

PHTHALAZINES (benzo-orthodiazines or benzopyridazines), in organic chemistry a group of heterocyclic compounds containing the ring complex shown in formula I. They are isomeric with the cinnolines (*q.v.*). The parent substance of the group, phthalazine, $C_8H_6N_2$, is best obtained from the condensation of ω-tetrabromorthoxylene with hydrazine (S. Gabriel, *Ber.*, 1893, 26, p. 2210), or by the reduction of chlorphthalazine with phosphorus and hydriodic acid (*Ber.*, 1897, p. 3024). It possesses basic properties and forms addition products with alkyl iodides. On oxidation with alkaline potassium permanganate it yields pyridazine dicarboxylic acid. Zinc and hydrochloric acid decompose it with formation of orthoxylylene diamine.

The keto-hydro derivative *phthalazone*, $C_8H_6ON_2$, (formula II.), is obtained by condensing hydrazine with orthophthalaldehydo-acid. On treatment with phosphorus oxychloride it yields a chlorphthalazine which with zinc and hydrochloric acid gives isoindole, C_8H_7N, and with tin and hydrochloric acid phthalimidine, C_8H_7ON, the second nitrogen atom being eliminated as ammonia.



I. Phthalazine.



II. Phthalazone.

PHTHALIC ACIDS, or Benzene Dicarboxylic Acids, $C_6H_4(CO_2H)_2$. There are three isomers: (1) ortho, or phthalic acid; (2) meta, or isophthalic acid; (3) para, or terephthalic acid.

Phthalic acid was obtained by Laurent in 1836 by oxidizing naphthalene tetrachloride, and, believing it to be a naphthalene derivative, he named it naphthalenic acid; Marignac determined its formula and showed Laurent's supposition to be incorrect, upon which Laurent gave it its present name. It is manufactured by oxidizing naphthalene tetrachloride (prepared from naphthalene, potassium chlorate and hydrochloric acid) with nitric acid, or, better, by oxidizing the hydrocarbon with fuming sulphuric acid, using mercury or mercuric sulphate as a catalyst (German pat. 91, 202). It also results on the oxidation of ortho-

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

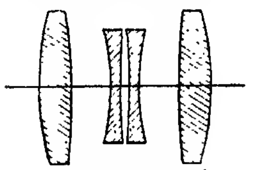


Fig. 53.—Beck-Steinheil "Unofocal."

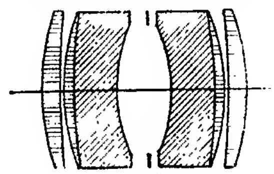

Fig. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f) = 0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°,

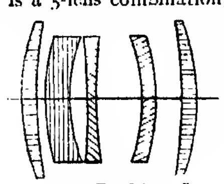

Fig. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Bonie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Trabei also dealt with the question, and in J. Zahn's *Oculus artificialis Telediopiricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephoto-

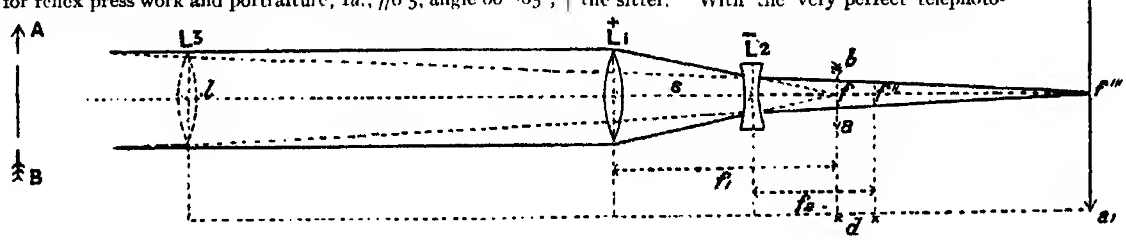

Fig. 56.

long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

graphic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

The structural variations presented by the phyllites are comparatively few. The most finely crystalline specimens have generally the most perfect parallel arrangement of their constituents. The foliation is generally flat or linear, but in some rocks is undulose or crumpled. From the imperfection of their cleavage phyllites are rarely suitable for roofing materials; their softness renders them valueless as road stones, but they are not uncommonly employed as inferior building materials. They are exceedingly common in all parts of the world where metamorphic rocks occur; as in the Scottish Highlands, Cornwall, Anglesey, north-west Ireland, the Ardennes, the Harz Mountains, Saxony, the Alps, Norway, the Appalachians, the Great Lakes district in America, &c. (J. S. F.)

PHYLLOXERA (Gr. φύλλον, leaf, and ξηρός, dry), a genus of insects belonging to the family of Aphidae, or Plant-lice, in the Homopterous section of the order Hemiptera. It is chiefly known from the causal relation of one of its species to the most serious of vine-diseases. The name was first given in 1834 to a plant-louse which was observed to "dry up the leaves" of oaks in Provence. About twenty-seven species are now known, all characterized by length not exceeding ·06 of an inch, flat wings, three articulations in the antennae, one or two articulations in the tarses, with digitules, but without cornicles on the abdomen.

The following full description of the only species which attacks the vine, the *Phylloxera vastatrix*, or grape-louse, is reprinted from the article VINE in the 9th edition of this encyclopaedia.

"The symptoms of the disease, by means of which an infected spot may be readily recognized, are as follows: The vines are stunted and bear few leaves, and those small ones. When the disease reaches an advanced stage the leaves are discoloured, yellow or reddish, with their edges turned back, and withered. The grapes are arrested in their growth and their skin is wrinkled. If the roots are examined numerous fusiform swellings are found upon the smaller rootlets. These are at first yellowish in colour and fleshy; but as they grow older they become rotten and assume a brown or black colour. If the roots on which these swellings occur be examined with a lens, a number of minute insects of a yellowish-brown colour are observed; these are the root-forms (radicola) of *Phylloxera* (fig. 1); they are about ·8 mm. long, of an oval outline and with a swollen body. No distinction between head, thorax and abdomen can be observed. The head bears small red eyes and a pair of three-jointed antennæ, the first two joints being short and thick, the third more elongated, with the end cut off obliquely and slightly hollowed out. Underneath, between the legs, lies the rostrum, which reaches back to the abdomen. The insect is fixed by this rostrum, which is inserted into the root of the vine for the purpose of sucking the sap. The abdomen consists of seven segments, and these as well as the anterior segments bear four rows of small tubercles on their dorsal surface. These root-dwelling insects are females, which lay parthenogenetic eggs. The insect is fixed by its proboscis, but moves its abdomen about and lays thirty to forty yellow eggs in small clusters. After the lapse of six, eight or twelve days, according to the temperature, the larvae hatch out of the eggs. These are light yellow in colour and in appearance resemble their mother, but with relatively larger appendages. They move actively about for a few days and then, having selected a convenient place on the young roots, insert their proboscis and become stationary. They moult five times, becoming with each change of skin darker in colour; in about three weeks they become adult and capable of laying parthenogenetic eggs. In this way the insect increases with appalling rapidity: it has been calculated that a single mother which dies after laying her eggs in March would have over 25,000,000 descendants by October. If, however, the insect were content with this method of reproduction the disease could be isolated by surrounding the infected patches with a deep ditch full of some such substance as coal-tar, which would prevent the insects spreading on to the roots of healthy vines. The fertility of the parthenogenetically produced insects would also diminish after a certain number of generations had been produced.

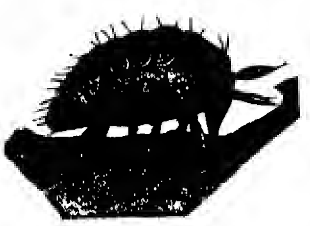

FIG. 1.—Root-inhabiting Form (Radicola) of *Phylloxera*, with proboscis inserted into tissue of root of vine.

As the summer wears on a second form of insect appears amongst the root-dwellers, though hatched from the same eggs as the form described above. These are the nymphs, destined to acquire wings; their body is more slender in outline, and at first they bear well-marked tubercles. After several moults the rudiments of two pairs of wings appear, and then the insect creeps up to the surface of the earth, and on to the vine. Here it undergoes its fifth and last moult, and appears as a winged female, capable of reproducing parthenogenetically. The winged form has a slender body with distinct head (fig. 2). The eyes are well developed, with numerous facets; the antennae have three joints, the terminal one shaped like that of the root-dwellers. The wings are transparent, with few nervures, and are well adapted for flight. The anterior pair reach far beyond the end of the abdomen; the posterior are narrower and not so long. These winged forms are about 1 mm. long. They fly about from July till October, living upon the sap of the vine, which is sucked up by the rostrum from the leaves or buds. They lay their parthenogenetically produced eggs in the angles of the veins of the leaves, in the buds, or, if the season is already far advanced, in the bark. In very damp or cold weather the insect remains in the ground near the surface, and deposits its eggs there. The eggs are very few in number and of two sizes, small and large (fig. 3, *b* and *c*). From the larger a female (fig. 4) is hatched in eight or ten days, and simultaneously, for the first time in the life-history of the *Phylloxera*, a male (fig. 3) appears from the smaller egg. Neither male nor female has wings; the rostrum is replaced by a functionless tubercle; and there is no alimentary canal. The female is larger than the male and differs from it and the other forms in the last joint of the antennae. The life of these sexual forms lasts but a few days, and is entirely taken up with reproduction. The female is fertilized by the male and three or four days later lays a single egg—the winter egg—and then dies. This egg is laid in the crevices of the bark of the vine, and as it is protectively coloured it is almost impossible to find it. Here the winter eggs remain undeveloped during the cold months; but in the following spring, as a rule in the month of April, they give birth to a female insect without wings, which resembles the root-dwelling forms, but has pointed antennae. These forms are termed the stock-mothers; they creep into the buds of the vine, and, as these develop into the young leaves, insert their proboscis into the upper side. By this means a gall is produced on the under side of the leaf.

FIG. 2. *Phylloxera.* Winged Female which lives on leaves and buds of vine, and lays parthenogenetically eggs of two kinds, one developing into a wingless female, the other into a male.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f)=0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a.*, *f*/6·5, angle 60°–65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

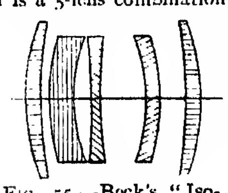

FIG. 55.—Beck's "Isostigmar."

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1866 by MM. Porro and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Telediottricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

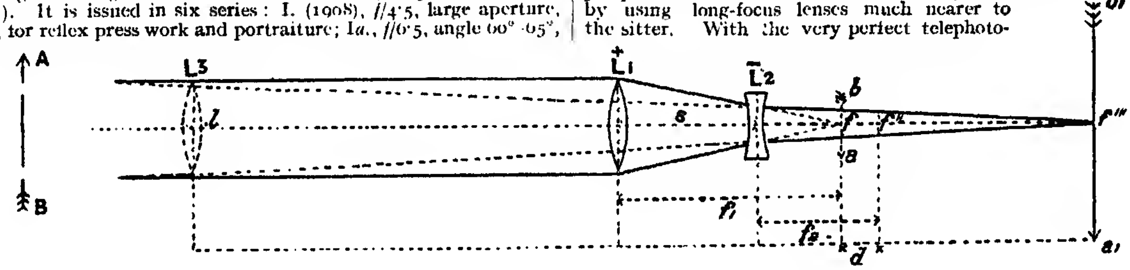

FIG. 56.

and practical men, bent on carrying them into action. The members of the group called themselves *les économistes*, but it is more convenient, because unambiguous, to designate them by the name *physiocrates* (Gr. φύσις, nature, and κρατεῖν, to rule), invented by P. S. Dupont de Nemours (1739–1817), who was one of their number. In this name, intended to express the fundamental idea of the school, much more is implied than the subjection of the phenomena of the social, and in particular the economic, world to fixed relations of coexistence and succession. This is the positive doctrine which lies at the bottom of all true science. But the law of nature referred to in the title of the sect was something quite different. The theological dogma which represented all the movements of the universe as directed by divine wisdom and benevolence to the production of the greatest possible sum of happiness had been transformed in the hands of the metaphysicians into the conception of a *jus naturae*, a harmonious and beneficial code established by the favourite entity of these thinkers, nature, antecedent to human institutions, and furnishing the model to which they should be made to conform.

The general political doctrine is as follows: Society is composed of a number of individuals, all having the same natural rights. If all do not possess (as some members of the negative school maintained) equal capacities, each can at least best understand his own interest, and is led by nature to follow it. The social union is really a contract between these individuals, the object of which is the limitation of the natural freedom of each just so far as it is inconsistent with the rights of the others. Government, though necessary, is a necessary evil; and the governing power appointed by consent should be limited to the amount of interference absolutely required to secure the fulfilment of the contract. In the economic sphere this implies the right of the individual to such natural enjoyments as he can acquire by his labour. That labour, therefore, should be undisturbed and unfettered, and its fruits should be guaranteed to the possessor; in other words, property should be sacred. Each citizen must be allowed to make the most of his labour; and therefore freedom of exchange should be ensured, and competition in the market should be unrestricted, no monopolies or privileges being permitted to exist.

The physiocrats then proceed with the economic analysis as follows: Only those labours are truly "productive" which add to the quantity of raw materials available for the purposes of man; and the real annual addition to the wealth of the community consists of the excess of the mass of agricultural products (including, of course, metals) over their cost of production. On the amount of this *produit net* depends the well-being of the community and the possibility of its advance in civilization. The manufacturer merely gives a new form to the materials extracted from the earth; the higher value of the object, after it has passed through his hands, only represents the quantity of provisions and other materials used and consumed in its elaboration. Commerce does nothing more than transfer the wealth already existing from one hand to another; what the trading classes gain thereby is acquired at the cost of the nation, and it is desirable that its amount should be as small as possible. The occupations of the manufacturer and merchant, as well as the liberal professions, and every kind of personal service, are "useful" indeed, but they are "sterile," drawing their income, not from any fund which they themselves create, but from the superfluous earnings of the agriculturist. The revenue of the state, which must be derived altogether from this net product, ought to be raised in the most direct and simplest way—namely, by a single impost of the nature of a land tax.

The special doctrine relating to the exclusive productiveness of agriculture arose out of a confusion between "value" on the one hand and "matter and energy" on the other. A. Smith and others have shown that the attempt to fix the character of "sterility" on manufactures and commerce was founded in error. And the proposal of a single *impôt territorial* falls to the ground with the doctrine on which it was based. But such influence as the school exerted depended little, if at all, on these peculiar tenets, which indeed some of its members did not hold. The effective result of its teaching was mainly destructive. It continued in a more systematic form the efforts in favour of the freedom of industry already begun in England and France. It was to be expected that the reformers should, in the spirit of the negative philosophy, exaggerate the vices of established systems; and there can be no doubt that they condemned too absolutely the economic action of the state, both in principle and in its historic manifestations, and pushed the *laissez-faire* doctrine beyond its just limits. But this was a necessary incident of their connexion with the revolutionary movement, of which they really formed one wing. In the course of that movement, the primitive social contract, the sovereignty of the people and other dogmas now seen to be untenable, were habitually invoked in the region of politics proper, and had a transitory utility as ready and effective instruments of warfare. And so also in the economic sphere the doctrines of natural rights of buying and selling, of the sufficiency of enlightened selfishness as a guide in mutual dealings, of the certainty that each member of the society will understand and follow his true interests, and of the coincidence of those interests with the public welfare, though they will not bear a dispassionate examination, were temporarily useful as convenient and serviceable weapons for the overthrow of the established order.

These conclusions as to the revolutionary tendencies of the school are not at all affected by the fact that the form of government preferred by Quesnay and some of his chief followers was what they called a legal despotism, which should embrace within itself both the legislative and the executive function. The reason for this preference was that an enlightened central power could more promptly and efficaciously introduce the policy they advocated than an assembly representing divergent opinions and fettered by constitutional checks and limitations. Turgot used the absolute power of the Crown to carry into effect some of his measures for the liberation of industry, though he ultimately failed because unsustained by the requisite force of character in Louis XVI. But what the physiocratic idea with respect to the normal method of government was appears from Quesnay's advice to the dauphin, that when he became king he should "do nothing, but let the laws rule," the laws having been, of course, first brought into conformity with the *jus naturae*. The partiality of the school for agriculture was in harmony with the sentiment in favour of "nature" and primitive simplicity which then showed itself in so many forms in France, especially in combination with the revolutionary spirit, and of which Rousseau was the most eloquent exponent. The members of the physiocratic group were undoubtedly men of thorough uprightness, and inspired with a sincere desire for the public good, especially for the material and moral elevation of the working classes. Quesnay was physician to Louis XV., and resided in the palace at Versailles; but in the midst of that corrupt court he maintained his integrity, and spoke with manly frankness what he believed to be the truth. And never did any statesman devote himself with greater singleness of purpose or more earnest endeavour to the service of his country than Turgot, who was the principal practical representative of the school.

The physiocratic school never obtained much direct popular influence, even in its native country, though it strongly attracted many of the more gifted and earnest minds. Its members, writing on dry subjects in an austere and often heavy style, did not find acceptance with a public which demanded before all things charm of manner in those who addressed it. The physiocratic tenets, which were in fact partly erroneous, were regarded by many as chimerical, and were ridiculed in the contemporary literature; as, for example, the *impôt unique* by Voltaire in his *L'Homme aux quarante écus*, which was directed in particular against P. P. Mercier-Larivière (1720–1794). It was justly objected to the group that they were too absolute in their view of things; they supposed, as Smith remarks in speaking of Quesnay, that the body politic could thrive only under one precise régime—that, namely, which they recommended—and

of a central negative lens, with cemented double front and back lenses (fig. 52). The negative lenses are of light silicate flint, the two positive of the heaviest baryta crown. Besides being a rapid universal lens, it is specially suitable for half-tone process work, with a large diaphragm (*E. Jb.*, 1903, p. 117). The "Dynar" (1903), *f*/6, angle 60°, is of somewhat similar construction, but differs from the "Heliar" in the positive lenses of the cemented pairs being outside instead of towards the central lens. It can only be used as a whole. It is made of hard colourless Jena glasses, giving great brilliancy and uniformity of illumination over a large angle, and is specially adapted for very rapid hand-camera work.

Dr R. Steinheil's "Unofocal" (1903), *f*/4·5 is a symmetrical doublet, each element consisting of two single separated lenses of equal refractive power and of equal focus of opposite signs, hence its name. Each half can be used as a single lens with small stops. In its construction a quite new principle was followed, the separation of the lenses fulfilling an important part in the colour correction, as explained by Conrad Beck in *Ph. Journ.* (1904), 44, p. 177. This plan satisfies the Petzval condition and removes its restrictions, so that a lens of *f*/4·5 can be produced with telescopic central definition, perfect freedom from distortion and flare over a flat field of 60°, with great equality of illumination (fig. 53). They are made by Messrs Beck in two series: II., *f*/4·5, for portraiture, rapid hand-camera work, telephotography and projection; and I., *f*/6, in which the lenses are closer together, for hand-camera work and general purposes. E. Arbeit's "Euryplan" anastigmats (1903), made by Schulze Bros., Potsdam, are apochromatic objectives of quite new construction, giving perfect definition with large apertures over a

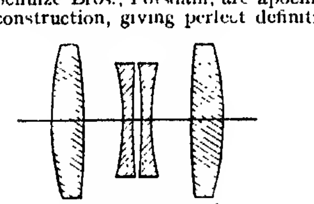

FIG. 53.—Beck-Steinheil "Unofocal."

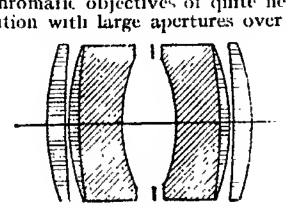

FIG. 54.—Euryplan, *f*/4·5.

wide angle, made in four series: I., *f*/4·5, angle 80°; II., *f*/5·6, angle 90°; III., *f*/6·8 to 7·5, angle 82°; IV., *f*/6·5. They are symmetrical doublets, each element consisting of three lenses, a new achromat formed of a biconvex of heavy baryta crown of high refractivity and low dispersion, separated by an air space from a positive meniscus of the same baryta crown, with its concave side towards the diaphragm. In series I., *f*/4·5, the two positives are placed outside (fig. 54), in series II. and III. they are inside. The single elements are fully corrected astigmatically and chromatically, and can be used singly at double the focus (*E. Jb.* 1904, p. 35).

Beck's "Isostigmar" (1907) is a new anastigmat showing a distinct departure from the ordinary principles of construction, in that it does not fulfil the Petzval condition that the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices should be equal to zero, or $\Sigma(1/\mu f) = 0$. It is a 5-lens combination, two separated thin single lenses in the front element and three in the back (fig. 55). In departing from the Petzval condition very low power lenses can be used, thus reducing the initial errors to be corrected; no individual component having a shorter focal length than one-half that of a complete objective. A special feature is the excellent correction of the oblique spherical aberrations and central aberrations, giving a practically flat field without astigmatism over angles from 60° to 90°. The half combinations can also be used alone with diaphragms as long focus lenses of different foci (*Ph. Journ.* 1907, 47, p. 191). It is issued in six series: I. (1908), *f*/4·5, large aperture, series, for reflex press work and portraiture; I*a*., *f*/6·5, angle 60°-65°, long focus, for portraiture, &c.; II., *f*/5·8, angle 70°, for general use, III. *f*/7·7, angle 65°, similar to II. but less rapid; IV. *f*/6·3, angle 90°; wide angle, giving satisfactory definition at full aperture over an angle from 80° to 85°. Having such a large reserve of covering power the

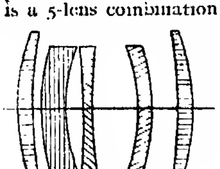

FIG. 55.—Beck's "Isostigmar."

latter is very useful when an extended use of the rising front is required, either at a wide or ordinary angle. V. (1908), *f*/11, "Process" lenses specially corrected to give a flat field for copying. They can be fitted with suitable reversing prisms. VI. (1908), *f*/5·6, variable portrait lenses, adjustable for sharp or soft definition from the back of the camera while focusing.

The above represent the principal types of anastigmats, but many more objectives of the kind, triple or quadruple, cemented or uncemented, with air-spaces, in many modifications, have been issued by English and foreign makers.

6. *Telephotographic Objectives.*—For some years past special objectives, or attachments, have been constructed for photographing near or distant objects on an enlarged scale with an ordinary camera, the extension required being very much less than would be needed to obtain an image of the same size with an ordinary long-focus lens without enlargement. They consist of a combination of a positive converging with a negative dispersing lens, by which the image is picked up and enlarged to varying degrees, according to the system of lenses used and the extension given to the camera, thus producing the same effect as a positive lens of very much longer focus. Enlarged images of this kind can also be made by a combination of two converging lenses, one of them forming an image of the object, which is received on the other of shorter focus and projected on the sensitive plate, being enlarged more or less according to the optical conditions and relative positions of the lenses and sensitive plate. The photoheliographs at Greenwich and other solar observatories, designed by Warren de la Rue, are on this principle. Portable apparatus of the kind was made in 1860 by MM. Bonie and de Tournemire, and later by Jarret, but this system requires much greater extension of the camera, entailing more loss of intensity of the image, and has never come into use.

The modern telephotographic combination is generally looked upon as an application of the principle of the "Barlow" lens, but it really goes back to the Galilean telescope (*c.* 1610). J. B. Porta mentions the combination of concave and convex lenses for giving enlarged and clearer images of near and distant objects (*Magia Naturalis*, lib. 17, cap. 10, 1589). J. Kepler showed that by a combination of a convex with a concave lens images of objects could be depicted on paper of a larger size than by the convex lens alone, but reversed (*Dioptrice, Prob.* cv. 1611). Christopher Scheiner made use of the same principle in his "Helioscope" for solar observations (*Rosa Ursina*, cap. vii. 1630). F. M. Deschales and P. Z. Traber also dealt with the question, and in J. Zahn's *Oculus artificialis Teledioptricus* (1686) we find figured a reflecting camera fitted with a compound enlarging lens on this principle. In his *Nova Dioptrica* (1692), W. Molyneux has given some interesting problems for calculating the position of the compound focus of a convex with a concave lens, also the angles subtended by an object on the focal plane. If for the simple uncorrected glasses then used we substitute a system of photographically corrected positive and negative lenses, suitably mounted, and put a sensitive plate in place of the paper, we have the modern telephotographic arrangement. I. Porro seems to have been the first to use a combination of this kind for photographing an eclipse in 1857, and later for terrestrial objects. It consisted of a small achromatic single lens combined with a concave lens. Many attempts were afterwards made in France, and also in England, to utilize the principle, but special lenses for the purpose were not available. Ad. Steinheil constructed one in 1889 for the Brussels Observatory, and another in 1890 for the Marine Department in Berlin. In 1891, curiously enough, three such combinations were worked out quite independently and patented, by T. R. Dallmeyer in London, A. Miethe in Berlin and A. Duboscq in Paris. Since that time these combinations have been greatly improved by increase in the working apertures and reduction in size and weight, so that they can be used in hand cameras. They are exceedingly valuable for obtaining details of inaccessible objects at a distance, whether architectural or topographical, and for photographing animals without approaching them too closely. Large portraits can also be taken with much better perspective effects and more conveniently than by using long-focus lenses much nearer to the sitter. With the very perfect telephotographic objectives now available the loss of intensity of illumination, which no doubt was the bar to early progress in this direction, has been overcome, and definition has also been improved, so that snapshots can readily be made with combinations of high intensity, while

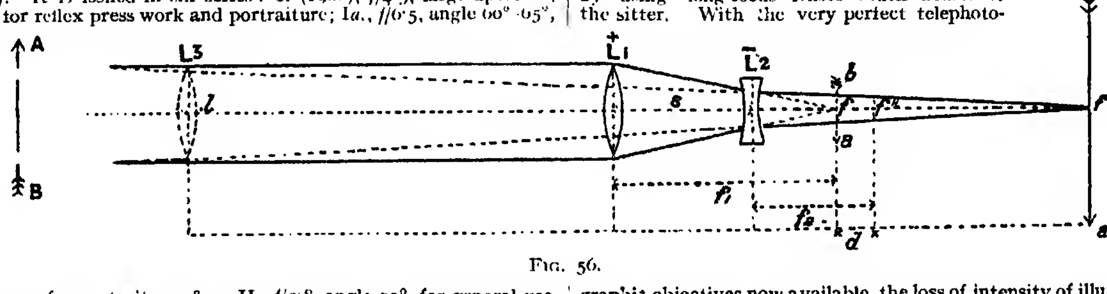

FIG. 56.

possible to tell habits from the aspect (cf. Ecclus. xix. 29, 30). Polemon (*c.* A.D. 150) compiled a treatise (published 1534, in Latin) on the subject, similar in character to that of Aristotle; but he excels in graphic descriptions of different dispositions, and differs only from Aristotle in some of his animal comparisons. A more important work was written by a converted Jew, Adamantius, about A.D. 415. This is in two books, the first on the expression of the eye, the second on physiognomy in general, mostly Aristotelian in character.

Among the Latin classical authors Juvenal, Suetonius and Pliny in well-known passages refer to the practice of physiognomy, and numerous allusions occur in the works of the Christian Fathers, especially Clement of Alexandria and Origen (for example, the familiar passage in his work against Celsus, i. 33).[1]

While the earlier classical physiognomy was chiefly descriptive, the later medieval authors particularly developed the predictive and astrological side, their treatises often digressing into chiromancy, onychomancy, clidomancy, podoscopy, spasmatomancy, and other branches of prophetic folk-lore and magic.

Along with the medical science of the period the Arabians contributed to the literature of physiognomy; 'Ali b. Ragel wrote a book on naevi; Rhazes (1040) devoted several chapters to it; and Averroes (1165) made many references to it in his *De sanitate*, p. 82 (Leiden, 1537). Avicenna also makes some acute physiognomical remarks in his *De animalibus*, which was translated by Michael Scot about 1270. Among medieval writers Albertus Magnus (born 1205) devotes much of the second section of his *De animalibus* to physiognomy; but this chiefly consists of extracts from Aristotle, Polemon and Loxus. He does not enter into the animal comparisons of his predecessors, but occupies himself chiefly with simple descriptive physiognomy as indicative of character; and the same is true of the scattered references in the writings of Duns Scotus and Thomas Aquinas. The famous sage of Balwearie, Michael Scot, while court astrologer to the emperor Frederick II., wrote his treatise *De hominis phisiognomia*, much of which is physiological and of curious interest. It was probably composed about 1272, but not printed until 1477. This was the first printed work on the subject. Physiognomy also forms the third part of his work *De secretis naturae*. In 1335 Pietro d'Abano of Padua delivered in Paris a course of lectures on this subject (afterwards edited by Blondus, 1544), a few years before he was burned for heresy.

The 16th century was rich in publications on physiognomy. The works of the classical authors before mentioned were printed, and other treatises were published by John de Indagine, Cocles, Andreas Corvus, Michael Blondus, Janus Cornaro, Anselm Douxciel, Pompeius Ronnseus, Gratarolus, Lucas Gauricus, Tricassus, Cardanus, Taisnierus, Magnus Hund, Rothman, Johannes Padovanus, and, greatest of all, Giambattista della Porta. The earliest English works were anonymous: *On the Art of Foretelling Future Events by Inspection of the Hand* (1504), and *A Pleasant Introduction to the Art of Chiromancie and Physiognomie* (1588). Dr Thomas Hill's work, *The Contemplation of Mankynde, contayning a singular Discourse after the Art of Physiognomie*, published in 1571, is a quaintly written adaptation from the Italian authors of the day. The undated book on moles and naevi by "Merlin Britannicus," after the model of 'Ali ibn Ragel, is of about the same date.

The development of a more accurate anatomy in the 17th century seems to have diminished the interest in physiognomy, by substituting fact for fiction; and consequently the literature, though as great in quantity, became less valuable in quality. The principal writers of this age were T. Campanella, Clement, R. Goclenius, Timpler, J. E. Gallimard, Moldenarius, Septalius, Saunders, C. Lebrun (a precursor of Charles Bell), Elsholz, de la Bellière, J. Evelyn (in the appendix to *Numismata*), Baldus, Bulwer (in his *Pathomyotomia*), Fuchs, Spontoni, Ghiradelli, Chiaramonti, A. Ingegneri, Finella, De la Chambre, Zanardus, R. Fludd, and others of less importance.

The 18th century shows a still greater decline of interest in physiognomy. Historians of philosophy, like J. Meursius and Franz, re-edited some of the classical works, and G. G. Fülleborn reviewed the relation of physiognomy to philosophy. Indeed, the only name worthy of note is that of J. K. Lavater (*q.v.*). The other authors of this century are Peuschel, Spon, Schutz, Wegelin, J. Pernetti, Girtanner, Grohmann, and several anonymous writers, and from the anatomical side G. M. Lancisi, J. Parsons and Peter Camper. The popular style, good illustrations and pious spirit pervading the writings of Lavater have given to them a popularity they little deserved, as there is no system in his work, which chiefly consists of rhapsodical comments upon the several portraits. Having a happy knack of estimating character, especially when acquainted with the histories of the persons in question, the good pastor contrived to write a graphic and readable book, but one much inferior to Porta's or Aristotle's as a systematic treatise. The treatises of Nicolai and of Lichtenberg were written to refute his theory. With Lavater the descriptive school of physiognomists may be said to have ended, as the astrological physiognomy expired with De la Bellière. The few works which have since appeared, before the rise of the physiological school of Sir Charles Bell and Charles Darwin, are undeserving of notice, the development of phrenology having given to pure physiognomy the *coup de grâce* by taking into itself whatever was likely to live of the older science. The writers of the 19th century are Hörstig, Maas, Rainer, Thoné, A. Stöhr, Schler, Dr Rubels, Polli, Cardona, Mastriani, Diez, Carus, Piderit, Burgess and P. Gratiolet.

The physiological school of physiognomy was foreshadowed by Parsons and founded by Sir Charles Bell, whose *Essay on the Anatomy of the Expression*, published in 1806, was the first scientific study of the physical manifestation of emotions in the terms of the muscles which produce these manifestations. In the later editions of this essay the thesis is elaborated with greater detail. Moreau's edition of Lavater, in 1807, was somewhat along the same lines. In 1817 Dr Cross of Glasgow wrote his defence of a scientific physiognomy based on general physiological principles. The experiments of G. B. A. Duchenne (*Mécanisme de la physiognomie humaine*, Paris, 1862) showed that by the use of electricity the action of the separate muscles could be studied and by the aid of photography accurately represented. These observations confirmed by experimental demonstration the hypothetical conclusions of Bell. The machinery of expression having thus been indicated, the connexion of the physical actions and the psychical state was made the subject of speculation by Herbert Spencer (*Psychology*, 1855). These speculations were reduced to a system by Darwin (*Expression of Emotions*, 1872), who formulated and illustrated the following as fundamental physiognomical principles:—

1. Certain complex acts are of direct or indirect service, under certain conditions of the mind, in order to relieve or gratify certain sensations or desires; and whenever the same states of mind are induced the same sets of actions tend to be performed, even when they have ceased to be of use. 2. When a directly opposite state of mind is induced to one with which a definite action is correlated, there is a strong and involuntary tendency to perform a reverse action. 3. When the sensorium is strongly excited nerve-force is generated in excess, and is transmitted in definite directions, depending on the connexions of nerve-cells and on habit.

The last of these propositions is adversely criticized by P. Mantegazza as a truism, but it may be allowed to stand with the qualification that we are ignorant concerning the nature of the influence called "nerve-force." It follows from these propositions that the expression of emotion is, for the most part, not under control of the will, and that those striped muscles are the most expressive which are the least voluntary. To the foregoing may be added the following three additional propositions, so as to form a more complete expression of a physiognomical philosophy:—

4. Certain muscles concerned in producing these skin-folds become strengthened by habitual action, and when the skin diminishes

[1] For Scriptural allusions to physiognomy see Vecchius, *Observationes in div. script.* (Naples, 1641). Other classical references are contained in the *Prooemium* to the 1593 edition of the works of Baptista Portae.

in elasticity and fullness with advancing age, the wrinkles at right angles to the course of the muscular fibres become permanent. 5. To some extent habitual muscular action of this kind may, by affecting local nutrition, alter the contour of such bones and cartilages as are related to the muscles of expression. 6. If the mental disposition and proneness to action are inherited by children from their parents, it may be that the facility in, and disposition towards, certain forms of expression are in like manner matters of heredity.

Illustrations of these theoretic propositions are to be found in the works of Bell, Duchenne and Darwin, and in the later publications of Theodor Piderit, *Mimike und Physiognomik* (1886) and Mantegazza, *Physiognomy and Expression* (1890), to which the student may be referred for further information.

For information on artistic anatomy as applied to physiognomy see the catalogue of sixty-two authors by Ludwig Choulant, *Geschichte und Bibliographie der anatomischen Abbildung*, &c. (Leipzig, 1852), and the works of the authors enumerated above, especially those of Aristotle, Franz, Porta, Cardan, Corvus and Bulwer. For physiognomy of disease, besides the usual medical handbooks, see Cabuchet, *Essai sur l'expression de la face dans les maladies* (Paris, 1801); Mantegazza, *Physiology of Pain* (1893), and Polli, *Saggio di fisiognomonia e potognomonia* (1837). For ethnological physiognomy, see amongst older authors Gratarolus, and amongst moderns the writers cited in the various textbooks on anthropology, especially Schadow, *Physionomies nationales* (1835) and Park Harrison, *Journ. Anthrop. Inst.* (1883). The study of the physical characteristics of criminals is discussed at great length by Lombroso, *L'Uomo delinquente* (1897); Ferri, *L'Omicidio* (1895); von Baer, *Der Verbrecher* (1893); Laurent, *Les Habitués des prisons* (1890); and Havelock Ellis, *The Criminal* (1901). (A. MA.)

PHYSIOLOGUS, the title usually given to a collection of some fifty Christian allegories much read in the middle ages, and still existing in several forms and in about a dozen Eastern and Western languages. As nearly all its imagery is taken from the animal world, it is also known as the *Bestiary*. There can be hardly a doubt about the time and general circumstances of its origin. Christian teachers, especially those who had a leaning towards Gnostic speculations, took an interest in natural history, partly because of certain passages of Scripture that they wanted to explain, and partly on account of the divine revelation in the book of nature, of which also it was man's sacred duty to take proper advantage. Both lines of study were readily combined by applying to the interpretation of descriptions of natural objects the allegorical method adopted for the interpretation of Biblical texts. Now the early Christian centuries were anything but a period of scientific research. Rhetorical accomplishments were considered to be the chief object of a liberal education, and to this end every kind of learning was made subservient. Instead of reading Aristotle and other naturalists, people went for information to commonplace books like those of Aelian, in which scraps of folk-lore, travellers' tales and fragments of misapprehended science were set forth in an elegant style. Theological writers were not in the least prepared to question the worth of the marvellous descriptions of creatures that were current in the schools on the faith of authorities vaguely known as "the history of animals," "the naturalists," and "the naturalist" in the singular number (φυσιολόγος).[1] So they took their notions of strange beasts and other marvels of the visible world on trust and did their best to make them available for religious instruction. In some measure we find this practice adopted by more than one of the Fathers, but it was the Alexandrian school, with its pronounced taste for symbolism, that made the most of it. Clement himself had declared that natural lore, as taught in the course of higher Christian education according to the canon of truth, ought to proceed from "cosmogony" to "the theological idea,"[2] and even in the little that is left of the works of Origen we have two instances of the proceeding in question. And yet the fact that these reappear in the *Physiologus* would not suffice to stamp the work as a series of extracts from Alexandrian writings, as parallels of the same kind can be adduced from Epiphanius (*loc. cit.*) and Ephraem Syrus (*Opp. Syr.* ii. 17, 130). Father Cahier would even trace the book to Tatian, and it is true that that heresiarch mentions a writing of his own upon animals. Still, the context in which the quotation occurs makes it evident that the subject matter was not the nature of particular species nor the spiritual lessons to be drawn therefrom, but rather the place occupied by animal beings in the system of creation. On the other hand, the opinion of Cardinal Pitra, who referred the *Physiologus* to the more orthodox though somewhat peculiar teaching of the Alexandrians, is fully borne out by a close examination of the irregularities of doctrine pointed out in the *Physiologus* by Cahier, all of which are to be met with in Origen. The technical words by which the process of allegorizing is designated in the *Physiologus*, like ἑρμηνεία, θεωρία, ἀναγωγή, ἀλληγορία, are familiar to the students of Alexandrian exegesis. It has, moreover, been remarked that almost all the animals mentioned were at home in the Egypt of those days, or at least, like the elephant, were to be seen there occasionally, whereas the structure of the hedgehog, for instance, is explained by a reference to the sea-porcupine, better known to fish-buyers on the Mediterranean. The fables of the phoenix and of the conduct of the wild ass and the ape at the time of the equinox owe their origin to astronomical symbols belonging to the Nile country.[3] In both chapters an Egyptian month is named, and elsewhere the antelope bears its Coptic name of "antholops."

That the substance of the *Physiologus* was borrowed from commentaries on Scripture[4] is confirmed by many of the sections opening with a text, followed up by some such formula as "but the Physiologus says." When zoological records failed, Egypto-Hellenic ingenuity was never at a loss for a fanciful invention distilled from the text itself, but which to succeeding copyists appeared as part of the teaching of the original *Physiologus*. As a typical instance we may take the chapter on the ant-lion—not the insect, but an imaginary creature suggested by Job iv. 11. The exceptional Hebrew for a lion (*layish*) appeared to the Septuagint translators to call for a special rendering, and as there was said to exist on the Arabian coast a lion-like animal called "myrmex" (see Strabo xvi. 774; Aelian, *N.A.*, vii. 47) they ventured to give the compound noun "myrmekoleon." After so many years the commentators had lost the key to this unusual term, and only knew that in common Greek "myrmex" meant an ant. So the text "the myrmekoleon hath perished for that he had no nourishment" set them pondering, and others reproduced their meditations, with the following result: "The *Physiologus* relates about the ant-lion: his father hath the shape of a lion, his mother that of an ant; the father liveth upon flesh, and the mother upon herbs. And these bring forth the ant-lion, a compound of both, and in part like to either, for his fore part is that of a lion, and his hind part like that of an ant. Being thus composed, he is neither able to eat flesh like his father, nor herbs like his mother; therefore he perisheth from inanition"; the moral follows.

At a later period, when the Church had learnt to look with suspicion upon devotional books likely to provoke the scoffing of some and lead others into heresy, a work of this kind could hardly meet with her approval. A synod of Pope Gelasius, held in 496, passed censure, among others, on the "Liber Physiologus, qui ab haereticis conscriptus est et B. Ambrosii nomine signatus, apocryphus," and evidence has even been offered that a similar sentence was pronounced a century before. Still, in spite of such measures, the *Physiologus*, like the *Church History* of Eusebius or the *Pastor of Hermas*, continued to be read with general interest, and even Gregory the Great did not disdain to allude to it on occasion. Yet the Oriental versions, which had certainly nothing to do with the Church of Rome, show that there was no systematic revision made according to the catholic

[1] Origen, *Sel. in Jerem.* xvii. 11, ἐν τῇ περὶ ζῴων ἱστορίᾳ; Epiphan. *Adv. haer.* i. 3, p. 274 (ed. D. Petav.), ὥς φασιν οἱ φυσιολόγοι; Origen, *Hom.* xvii., in Gen. xliv. 9, "nam physiologus de catulo leonis scribit."

[2] *Strom.*, iv. p. 564 (ed. Potter), ἡ γοῦν κατὰ τὸν τῆς ἀληθείας κανόνα γνωστικῆς παραδόσεως φυσιολογία, μᾶλλον δὲ ἐποπτεία, ἐκ τοῦ περὶ κοσμογονίας ἤρτηται λόγου, ἐνθένδε ἀναβαίνουσα ἐπὶ τὸ θεολογικὸν εἶδος.

[4] Including the Apocrypha. See the Icelandic account of the elephant, also a decidedly Alexandrian fragment upon the μάργος, founded upon 4 Macc. i. 3, which has got into the scholia upon the *Odyssey* xviii. 2 (ii. 533, ed. Dindorf, Oxford, 1855).

standard of doctrine. The book remained essentially the same, albeit great liberties were taken with its details and outward form. There must have been many imperfect copies in circulation, from which people transcribed such sections as they found or chose, and afterwards completed their MS. as occasion served. Some even rearranged the contents according to the alphabet or to zoological affinity. So little was the collection considered as a literary work with a definite text that every one assumed a right to abridge or enlarge, to insert ideas of his own, or fresh scriptural quotations; nor were the scribes and translators by any means scrupulous about the names of natural objects, and even the passages from Holy Writ. *Physiologus* had been abandoned by scholars, and left to take its chance among the tales and traditions of the uneducated mass. Nevertheless, or rather for this very reason, its symbols found their way into the rising literature of the vulgar tongues, and helped to quicken the fancy of the artists employed upon church buildings and furniture.

The history of the *Physiologus* has become entwined from the beginning with that of the commentaries on the account of creation in Genesis. The principal production of this kind in our possession is the *Hexaemeron* of Basil, which contains several passages very like those of the *Physiologus*. For instance, in the seventh homily the fable of the nuptials of the viper and the conger-eel, known already to Aelian and Oppian, and proceeding from a curious misreading of Aristotle (*Hist. An.* v. 4, 540 b, Bekk.), serves to point more than one moral. Notwithstanding the difference in theology, passages of this kind could not but be welcome to the admirers of the Alexandrian allegories. In fact a medley from both Basil and the *Physiologus* exists under the title of the *Hexaemeron* of Eustathius; some copies of the first bear as a title Περὶ φυσιολογίας, and in a Milan MS. the "morals" of the *Physiologus* are ascribed to Basil. The Leyden Syriac is supplemented with literal extracts from the latter, and the whole is presented as his work. Other copies give the names of Gregory Theologus, Epiphanius, Chrysostom and Isidore.

As far as can be judged, the emblems of the original *Physiologus* were the following: (1) the lion (footprints rubbed out with tail; sleeps with eyes open; cubs receive life only three days after birth by their father's breath); (2) the sun-lizard (restores its sight by looking at the sun); (3) the charadrius (Deut. xiv. 16; presages recovery or death of patients); (4) the pelican (recalls its young to life by its own blood); (5) the owl (or nyktikorax; loves darkness and solitude); (6) the eagle (renews its youth by sunlight and bathing in a fountain); (7) the phoenix (revives from fire); (8) the hoopoe (redeems its parents from the ills of old age); (9) the wild ass (suffers no male besides itself); (10) the viper (born at the cost of both its parents' death); (11) the serpent (sheds its skin; puts aside its venom before drinking; is afraid of man in a state of nudity; hides its head and abandons the rest of its body); (12) the ant (orderly and laborious; prevents stored grain from germinating; distinguishes wheat from barley on the stalk); (13) the sirens and onocentaurs (Isa. xiii. 21, 22; compound creatures); (14) the hedgehog (pricks grapes upon its quills); (15) the fox (catches birds by simulating death); (16) the panther (spotted skin; enmity to the dragon; sleeps for three days after meals; allures its prey by sweet odour); (17) the sea-tortoise (or aspidochelone; mistaken by sailors for an island); (18) the partridge (hatches eggs of other birds); (19) the vulture (assisted in birth by a stone with loose kernel); (20) the ant-lion (able neither to take the one food nor to digest the other); (21) the weasel (conceives by the mouth and brings forth by the ear); (22) the unicorn (caught only by a virgin); (23) the beaver (gives up its testes when pursued); (24) the hyaena (a hermaphrodite); (25) the otter (enhydris; enters the crocodile's mouth to kill it); (26) the ichneumon (covers itself with mud to kill the dragon; another version of No. 25); (27) the crow (takes but one consort in its life); (28) the turtle-dove (same nature as No. 27); (29) the frog (either living on land and killed by rain, or in the water without ever seeing the sun); (30) the stag (destroys its enemy the serpent); (31) the salamander (quenches fire); (32) the diamond (powerful against all danger); (33) the swallow (brings forth but once; misreading of Aristotle, *Hist. An.* v. 13); (34) the tree called peridexion (protects pigeons from the serpent by its shadow); (35) the pigeons (of several colours; led by one of them, which is of a purple or golden colour); (36) the antelope (or hydrippus; caught by its horns in the thicket); (37) the fire-flints (of two sexes; combine to produce fire); (38) the magnet (adheres to iron); (39) the saw-fish (sails in company with ships); (40) the ibis (fishes only along the shore); (41) the ibex (descries a hunter from afar); (42) the diamond again (read "carbuncle"; found only by night); (43) the elephant (conceives after partaking of mandrake; brings forth in the water; the young protected from the serpent by the father; when fallen is lifted up only by a certain small individual of its own kind); (44) the agate (employed in pearl-fishing); (45) the wild ass and ape (mark the equinox); (46) the Indian stone (relieves patients of the dropsy); (47) the heron (touches no dead body, and keeps to one dwelling-place); (48) the sycamore (or wild fig; grubs living inside the fruit and coming out); (49) the ostrich (devours all sorts of things; forgetful of its own eggs). Besides these, or part of them, certain copies contain sections of unknown origin about the bee, the stork, the tiger, the woodpecker, the spider and the wild boar.

The Greek text of the *Physiologus* exists only in late MSS., and has to be corrected from the translations. In Syriac we have a full copy in a 12th-century Leyden MS., published in J. P. N. Land's *Anecdota syriaca*; thirty-two chapters with the "morals" left out in a very late Vatican copy, published by Tychsen; and about the same number in a late MS. of the British Museum (Add. 25878). In Armenian Pitra gave some thirty-two chapters from a Paris MS. (13th century). The Aethiopic exists both in London and Paris, and was printed at Leipzig by Dr Hommel in 1877. In Arabic we have fragments at Paris, of which Renan translated a specimen for the *Spicilegium solesmense*, and another version of thirty-seven chapters at Leiden, probably the work of a monk at Jerusalem, which Land translated and printed with the Syriac. The Latin MSS. of Bern are, after the Vatican glossary of Ansileubus, the oldest of which we know; there are others in several libraries, and printed editions by Mai, Heider and Cahier. Besides these, a few fragments of an old abridgment occur in Vallarsi's edition of Jerome's works (vol. xi. col. 218). A metrical *Physiologus* of but twelve chapters is the work of Theobaldus, probably abbot of Monte Cassino (A.D. 1022-1035). From this was imitated the Old-English fragment printed by Th. Wright, and afterwards by Maetzner; also the Old-French *Sensuyl le bestiaire d'amours*. The prose *Physiologus* was done into Old High German before 1000, and afterwards into rhyme in the same idiom; since Von der Hagen (1824) its various forms have found careful editors among the leading Germanists. The Icelandic, in a Copenhagen MS. of the 13th century, was printed by Professor Th. Möbius in his *Analecta norroena* (2nd ed., 1877); at the same time he gave it in German in Dr Hommel's Aethiopic publication. Some Anglo-Saxon metrical fragments are to be found in Grein's *Bibliothek*, vol. i. The Provençal (*c.* 1250), published in Bartsch's *Chrestomathie provençale*, omits the "morals," but is remarkable for its peculiarities of form. Before this there had been translations into French dialects, as by Philippe de Thaun (1121), by Guillaume, "clerc de Normandie," also, about the same period, by Pierre, a clergyman of Picardy. All the Old-French materials have not yet been thoroughly examined, and it is far from improbable that some versions of the book either remain to be detected or are now lost past recovery. A full account of the history of the *Physiologus* should also embrace the subjects taken from it in the productions of Christian art, the parodies suggested by the original work, *e.g.* the *Bestiaire d'amour* by Richard de Fournival, and finally the traces left by it upon the encyclopaedical and literary work of the later middle ages.

Nearly all the information now obtainable is to be found in the following works and such as are there quoted: *S. Epiphanius ad physiologum*, ed. Ponce de Leon (with woodcuts) (Rome, 1587); another edition, with copper-plates (Antwerp, 1588); *S. Eustathii in hexahemeron commentarius*, ed. Leo Allatius (Lyons, 1629; cf. H. van Herwerden, *Exercitt. Critt.*, pp. 180–182, Hague, 1862); *Physiologus syrus*, ed. O. G. Tychsen (Rotsock, 1795); *Classici auctores*, ed. Mai, vii. 585-596 (Rome, 1835); G. Heider, in *Archiv für Kunde österreich. Geschichtsquellen* ii. 545 seq. (Vienna, 1850); Cahier and Martin, *Mélanges d'archéologie*, &c. ii. 85 seq. (Paris, 1851), iii. 203 seq. (1853), iv. 55 seq. (1856); Cahier, *Nouveaux mélanges* (1874), p. 106 seq.; J. B. Pitra, *Spicilegium solesmense* iii., xlvii. seq., 338 seq., 416, 535 (Paris, 1855); Maetzner, *Altengl. Sprachproben* (Berlin, 1867), vol. i. pt. i. p. 55 seq.; J. Victor Carus, *Gesch. der Zoologie* (Munich, 1872), p. 109 seq.; J. P. N. Land, *Anecdota syriaca* (Leiden, 1874), iv. 31 seq., 115 seq., and in *Verslagen en Mededeelingen der kon. Akad. van Wetenschappen*, 2nd series, vol. iv. (Amsterdam, 1874); Möbius and Hommel in their

publications quoted above. See also Lauchert, *Geschichte des Physiologus* (Strassburg, 1889) and E. Peters, *Der griechische Physiologus und seine orientalischen Übersetzungen* (Berlin, 1898).

PHYSIOLOGY (from Gr. φύσις, nature, and λόγος, discourse), the science or theory of the properties, processes and functions of living organisms. Physiology is distinguished from anatomy as dealing specifically with the functions of an organism, rather than its structure. The two main branches of the science are animal and plant (vegetable) physiology, and in animal physiology that of man stands out as primarily associated with the word.

History of Theory.

Ever since men began to take a scientific interest in the problems of life two distinct rival explanatory principles of vital phenomena have claimed attention: a natural and a mystical principle. The first outcome of the scientific attempt to explain vital phenomena after the natural method and by a unitary principle was the doctrine of the *Pneuma*, held by the followers of Hippocrates, which found its clearest expression in Galen's system. According to this doctrine, the origin of all vital phenomena was a very fine substance, the Pneuma, which was supposed to exist in atmospheric air, to be inhaled into the lungs of man, and thus through the blood to reach all the parts of the body, where it produced vital phenomena. This doctrine—an attempt to explain the phenomena of life which was not altogether natural, but even materialistic—was accepted by the middle ages together with Galen's system. With its translation into the Latin *spiritus*, however, the conception of the Pneuma lost its original force. The *spiritus animales* of the middle ages developed ere long into mystical powers, the result being the explanation of vital phenomena by a supernatural theory. Not until the scientific renaissance of the 16th and 17th centuries did views again undergo a change. After the establishment of a scientific method in physiology by William Harvey, and the development of Descartes' mechanical system of regarding living bodies, the natural explanation of vital phenomena once more universally found favour. Two schools arose, which endeavoured by dissimilar methods to find a mechanical explanation of vital phenomena: the *iatrophysical*, originating with the gifted and versatile Borelli, and the *iatrochemical*, founded by the Dutchman, F. de la Boë (Sylvius). But when both chemical and physical methods of explanation failed at such problems as, for instance, irritability and evolution, another change in opinion took place. By degrees there emerged once more the tendency to explain vital phenomena by mystical means, finding expression in the *Animism* of Stahl, to quote an example; and in the second half of the 18th century *Vitalism*, originating in France, began its victorious march throughout the whole scientific world. Again the opinion came to be entertained that the cause of vital phenomena was a mystical power (*force hypermécanique*)—that "vital force" which, neither physical nor chemical in its nature, was held to be active in living organisms only. Vitalism continued to be the ruling idea in physiology until about the middle of the 19th century, and its supremacy was only gradually overthrown by the great discoveries in natural science of that century. The chemical discoveries resulting from Wöhler's synthesis of urea first showed that typical products of the animal body, the production of which had hitherto been supposed to be solely the result of the operation of vital force, could be obtained artificially by purely chemical methods. Then above all came the discovery of the law of the Conservation of Energy by Robert Mayer (1814–1878) and Hermann von Helmholtz (1821–1894), and its application to the living organism by Mayer, Helmholtz, Pierre Louis Dulong (1785–1838), Edward Frankland, Max Rubner and others, to prove that the manifestations of energy by the organism are simply the result of the quantity of potential energy received into the body by means of food. Finally, the stupendous results arrived at by Darwin and the establishment of the fundamental law of "biogenesis" by Ernst Haeckel, prepared the way for a natural explanation of the enigma of evolution and structure of organisms. Thus by the second half of the 19th century the doctrine of vital force was definitely and finally overthrown to make way for the triumph of the natural method of explaining vital phenomena, which down to the present time has continued to spread and flourish with an unparalleled fertility. It would, it is true, appear as if in our day, after the lapse of half a century, mystical tendencies were again disposed to crop up in the investigation of life. Here and there is heard once more the watchword of Vitalism. But all the so-called *neo-vitalistic* efforts—such as those of Alexander von Bunge (1803–1890), Georg Evon Rindfleisch (b. 1835), Johannes Reinke (b. 1849) and others—have nothing to do with the old vitalism. They originate solely in a widespread confusion with regard to the boundaries of natural science, their principal tendency being to amalgamate psychological and speculative questions with problems of purely natural science. In the face of all these efforts, which by their unfortunate designations of Vitalism and Neo-vitalism give rise to entirely false conceptions, and which by their intermingling of psychological questions and questions of natural science have led to mere confusion in research, it is essential that natural philosophy should be called upon to realize its own limits, and above all clearly to understand that the sole concern of physical science is the investigation of the phenomena of the material world. Physiology, as the doctrine of life, must therefore confine itself to the material vital phenomena of organisms. It is self-evident, however, that only such laws as govern the material world will be found governing material vital phenomena—the laws, that is, which have hitherto been brought to their most exact and most logical development by physics and chemistry, or, more generally speaking, by mechanics. The explanatory principles of vital phenomena must therefore be identical with those of inorganic nature—that is, with the principles of mechanics.

Ultimate Elements of Life.

The investigation of vital phenomena in this sense requires, in the first place, an exact knowledge of the substratum in which these phenomena are manifested, just as in chemistry and physics a thorough knowledge of the composition of the material world is a necessary premise to the investigation of the phenomena of inorganic nature. The knowledge of the composition and structure of organisms has in the course of the scientific development of anatomy attained to an ever-increasing minuteness of detail, without having as yet reached a definite limit. The last important step in this direction was the discovery by Matthias Jakob Schleiden (1804–1881) and Theodor Schwann (1810–1882) that all organisms are built up of elementary living structural components, namely of cells (see CYTOLOGY). The details of the anatomical construction of organisms are described under various appropriate headings, and a general guide to these will be found under ANATOMY and ZOOLOGY. We would here merely point out that a cell is the simplest particle of living substance which appears to be permanently capable of life. Different elements are essential, however, to the existence of the cell—two, at least, so far as has hitherto been discovered—the protoplasm and the nucleus. It must at present be regarded as at least very doubtful whether the *centrosome*, which in recent times it has been possible to demonstrate as existing in very many cells, and which appears sometimes in the protoplasm, sometimes in the nucleus, is a general and third independent cell-constituent. On the other hand, the number of special constituent parts which appear in various cell-forms is very large. A question which has long been discussed, and which has received special and animated attention, is that with regard to the finer structure of the cells—with regard, that is, to the protoplasm and the nucleus lying in it. Views on this subject have diverged very widely, and several totally diverse theories have been opposed to one another. One theory maintains that the living cell-substance has a reticular structure; another, that it is fibrillous. According to a third theory, the essence of the construction of the cell-substance lies in the granules which it contains; and according to a fourth, it lies in the ground-substance in which these granules are embedded. One view holds this ground substance to be homogeneous, another regards it as possessing a fine foam-structure. It may at present be regarded as

incontrovertible that living substance is more or less fluid, and that there does not exist any *general* structure for all cell-forms. But in some special cases all the theories which have been quoted are to a certain extent correct. In different cells there are reticular, fibrillous and granular differentiations respectively, and differentiations in foam-structure; in many cells, however, the protoplasm appears to be beyond doubt homogeneous and without a distinct structure, and only under certain conditions to assume changing structures. But the fact which is of most importance for the right understanding of vital phenomena is that the cell-substance is always more or less fluid, for only in a fluid substratum can such intense chemical processes be enacted as are to be found in every living cell.

Where the analytical powers of the microscope in anatomy can go no farther, chemical analysis of the composition of the cell steps in. By its means the discovery is made that there is no *elementary* difference between organic and inorganic nature, for only such chemical elements as are known to exist in the inorganic world are found in the organic. On the other hand, however, the living cell-substance possesses chemical *compounds* which find analogues nowhere in inorganic nature. The characteristic organic substances which are present in every cell are proteids and proteid-compounds. Besides these there occur, widely disseminated, carbohydrates, fats and other organic substances, which partly originate in the decomposition of proteids and their compounds, and are partly used for their construction. Lastly, there are in addition great quantities of water and some inorganic salts.

General Phenomena of Life.

Such are the structure and composition of the substratum in which vital phenomena play their part. When we consider vital phenomena themselves in the various living organisms—in protista, plants, animals, man—there appears an incalculable diversity of phenomena. Here, however, as in the case of the structure of organisms, we have to analyse and to penetrate ever farther and deeper till we reach the fundamental phenomena. We then find that the great variety of vital manifestations may be traced back to a few fundamental general groups, which are precisely the same groups of phenomena as those to be observed in inorganic nature. All the processes that take place in the organic world may be regarded from the three different standpoints of their changes in substance, in energy and in form; for substance, energy and form are all necessary to our conception of matter. Accordingly, the general elementary vital phenomena likewise fall into three groups—metabolism, the mechanism of energy, and the assumption of form. Every cell, so long as it is living, takes in certain substances from its environment, submits them to chemical transformation in its interior, and gives out other substances. This *metabolism* is manifested in several special functions—in nutrition and digestion, respiration and circulation, secretion and excretion. The essence of the whole process is the fact that while out of these ingested stuffs living substance is always again being formed by the living substance which already exists, it is itself continually undergoing decomposition, and the products of this decomposition are what the cell gives off again to the outside. With metabolism, however, there is inseparably associated a *transformation of energy.* These substances taken in by the cell contain a large quantity of potential energy, which is transformed into kinetic energy. This has for its result the manifold activities of the organism, more especially motion, heat, electricity and light. Finally, the chemical transformations in living substance may also manifest themselves outwardly in *changes of form,* as is the case generally in the matter of growth, reproduction and development. The three general elementary groups of vital phenomena are therefore in reality merely the expression of the various aspects of one and the same process —of the actual vital process itself. The ultimate object of all physiology is to discover what this vital process is—that is to say, what is the exact cause of these manifold vital phenomena—a goal from which it is at the present day still very remote.

Conditions of Life.

As every physical and chemical phenomenon of inorganic nature occurs only under distinct conditions, so vital phenomena are also dependent upon certain conditions of life. Every living body, every living cell, requires food, water, oxygen, and, further, a certain temperature and a certain pressure in its environment. These are the *general* conditions of life. But the *special* conditions on which depends the continued existence of the individual forms of organism are as numerous as the forms of organisms themselves. Now, just as the physicist or chemist varies those conditions under which a phenomenon occurs in order to get at its causes, so does the physiologist try to experiment with vital phenomena, altering the vital conditions: and testing the changes which are thereby produced. The great importance of this method consists in the power it gives the experimenter of analysing vital phenomena systematically from definite points of view. Every change in its normal vital conditions which produces any effect whatsoever upon an organism is termed a *stimulus.* This is the only general definition we have for a conception which is of such vast importance to physiology. According to it, experimental physiology is entirely a physiology of stimuli. It further follows from this conception of stimulation that there must be an enormous multiplicity of stimuli, since each particular vital condition may be subjected to some change capable of acting upon it as a stimulus. But, besides this, other factors may be brought to bear upon organisms which have absolutely no place among their vital conditions: for instance, many chemical reagents and electric currents. These influences come under the general definition of stimulus, because they likewise imply a change in the conditions under which the organism lives. From their qualitative nature stimuli are distinguished as chemical, thermal, photic, mechanical and electrical. Each of these several varieties may, however, be applied quantitatively in various degrees of intensity, and may in consequence produce quite different results. This opens up to experimental physiology a vast field of research. But the physiology of stimulation is not only of the greatest value as a *means* of research: its importance is much increased by the fact that in nature itself stimuli are everywhere and constantly acting upon the organism and its parts. Hence the investigation of their action comes to be not merely a *means,* but a direct *end* of research.

Actions of Stimuli.

Although it is not at present possible to define all the laws that govern stimulation, on the one hand because the number of stimulating effects known to us in the whole organic world is as yet too limited, and on the other because those already known have not yet been thoroughly analysed, yet it is within our power to classify stimulating effects according to their various characteristics, and to ascertain a few facts concerning their general and fundamental conformity to law. The first fact, apparent from a glance at a great many of the various forms of stimulation, is that all their effects are manifested in either a *quantitative* or a *qualitative* alteration of the characteristic vital phenomena of each living object. The quantitative is the usual mode of action of stimuli. It is generally found that a stimulus either increases or diminishes the intensity of vital phenomena. In the first case the effect is one of excitation; in the second of depression. It is the more important to bear in mind this twofold operation of stimuli, owing to the fact that in former times physiologists were very apt to conceive of excitation and stimulation as identical. It is now, however, an undisputed fact that depression may also occur as a typical effect of stimulation. This is most apparent in cases where the same stimulus that produces excitation may on being applied for a longer period and with greater intensity, produce depression. Thus narcotics (alcohol, ether, chloroform, morphia, &c.) on certain forms of living substance produce the phenomena of excitation when their action is weak, whereas when it is stronger they produce complete depression. Thus, likewise, temperature stimuli act differently upon vital phenomena according to the degree of temperature: very low temperatures depressing,

publications quoted above. See also Lauchert, *Geschichte des Physiologus* (Strassburg, 1889) and E. Peters, *Der griechische Physiologus und seine orientalischen Übersetzungen* (Berlin, 1898).

PHYSIOLOGY (from Gr. φύσις, nature, and λόγος, discourse), the science or theory of the properties, processes and functions of living organisms. Physiology is distinguished from anatomy as dealing specifically with the functions of an organism, rather than its structure. The two main branches of the science are animal and plant (vegetable) physiology, and in animal physiology that of man stands out as primarily associated with the word.

History of Theory.

Ever since men began to take a scientific interest in the problems of life two distinct rival explanatory principles of vital phenomena have claimed attention: a natural and a mystical principle. The first outcome of the scientific attempt to explain vital phenomena after the natural method and by a unitary principle was the doctrine of the *Pneuma*, held by the followers of Hippocrates, which found its clearest expression in Galen's system. According to this doctrine, the origin of all vital phenomena was a very fine substance, the Pneuma, which was supposed to exist in atmospheric air, to be inhaled into the lungs of man, and thus through the blood to reach all the parts of the body, where it produced vital phenomena. This doctrine—an attempt to explain the phenomena of life which was not altogether natural, but even materialistic—was accepted by the middle ages together with Galen's system. With its translation into the Latin *spiritus*, however, the conception of the Pneuma lost its original force. The *spiritus animales* of the middle ages developed ere long into mystical powers, the result being the explanation of vital phenomena by a supernatural theory. Not until the scientific renaissance of the 16th and 17th centuries did views again undergo a change. After the establishment of a scientific method in physiology by William Harvey, and the development of Descartes' mechanical system of regarding living bodies, the natural explanation of vital phenomena once more universally found favour. Two schools arose, which endeavoured by dissimilar methods to find a mechanical explanation of vital phenomena: the *iatrophysical*, originating with the gifted and versatile Borelli, and the *iatrochemical*, founded by the Dutchman, F. de la Boë (Sylvius). But when both chemical and physical methods of explanation failed at such problems as, for instance, irritability and evolution, another change in opinion took place. By degrees there emerged once more the tendency to explain vital phenomena by mystical means, finding expression in the *Animism* of Stahl, to quote an example; and in the second half of the 18th century *Vitalism*, originating in France, began its victorious march throughout the whole scientific world. Again the opinion came to be entertained that the cause of vital phenomena was a mystical power (*force hypermécanique*)—that "vital force" which, neither physical nor chemical in its nature, was held to be active in living organisms only. Vitalism continued to be the ruling idea in physiology until about the middle of the 19th century, and its supremacy was only gradually overthrown by the great discoveries in natural science of that century. The chemical discoveries resulting from Wöhler's synthesis of urea first showed that typical products of the animal body, the production of which had hitherto been supposed to be solely the result of the operation of vital force, could be obtained artificially by purely chemical methods. Then above all came the discovery of the law of the Conservation of Energy by Robert Mayer (1814–1878) and Hermann von Helmholtz (1821–1894), and its application to the living organism by Mayer, Helmholtz, Pierre Louis Dulong (1785–1838), Edward Frankland, Max Rubner and others, to prove that the manifestations of energy by the organism are simply the result of the quantity of potential energy received into the body by means of food. Thus by the second half of the 19th century the doctrine of vital force was definitely and finally overthrown to make way for the triumph of the natural method of explaining vital phenomena, which down to the present time has continued to spread and flourish with an unparalleled fertility. It would, it is true, appear as if in our day, after the lapse of half a century, mystical tendencies were again disposed to crop up in the investigation of life. Here and there is heard once more the watchword of Vitalism. But all the so-called *neo-vitalistic* efforts—such as those of Alexander von Bunge (1803–1890), Georg Evon Rindfleisch (b. 1835), Johannes Reinke (b. 1849) and others—have nothing to do with the old vitalism. They originate solely in a widespread confusion with regard to the boundaries of natural science, their principal tendency being to amalgamate psychological and speculative questions with problems of purely natural science. In the face of all these efforts, which by their unfortunate designations of Vitalism and Neo-vitalism give rise to entirely false conceptions, and which by their intermingling of psychological questions and questions of natural science have led to mere confusion in research, it is essential that natural philosophy should be called upon to realize its own limits, and above all clearly to understand that the sole concern of physical science is the investigation of the phenomena of the material world. Physiology, as the doctrine of life, must therefore confine itself to the material vital phenomena of organisms. It is self-evident, however, that only such laws as govern the material world will be found governing material vital phenomena—the laws, that is, which have hitherto been brought to their most exact and most logical development by physics and chemistry, or, more generally speaking, by mechanics. The explanatory principles of vital phenomena must therefore be identical with those of inorganic nature—that is, with the principles of mechanics.

Ultimate Elements of Life.

The investigation of vital phenomena in this sense requires, in the first place, an exact knowledge of the substratum in which these phenomena are manifested, just as in chemistry and physics a thorough knowledge of the composition of the material world is a necessary premise to the investigation of the phenomena of inorganic nature. The knowledge of the composition and structure of organisms has in the course of the scientific development of anatomy attained to an ever-increasing minuteness of detail, without having as yet reached a definite limit. The last important step in this direction was the discovery by Matthias Jakob Schleiden (1804–1881) and Theodor Schwann (1810–1882) that all organisms are built up of elementary living structural components, namely of cells (see CYTOLOGY). The details of the anatomical construction of organisms are described under various appropriate headings, and a general guide to these will be found under ANATOMY and ZOOLOGY. We would here merely point out that a cell is the simplest particle of living substance which appears to be permanently capable of life. Different elements are essential, however, to the existence of the cell—two, at least, so far as has hitherto been discovered—the protoplasm and the nucleus. It must at present be regarded as at least very doubtful whether the *centrosome*, which in recent times it has been possible to demonstrate as existing in very many cells, and which appears sometimes in the protoplasm, sometimes in the nucleus, is a general and third independent cell-constituent. On the other hand, the number of special constituent parts which appear in various cell-forms is very large. A question which has long been discussed, and which has received special and animated attention, is that with regard to the finer structure of the cells—with regard, that is, to the protoplasm and the nucleus lying in it. Views on this subject have diverged very widely, and several totally diverse theories have been opposed to one another. One theory maintains that the living cell-substance has a reticular structure; another, that it is fibrillous. According to a third theory, the essence of the construction of the cell-substance lies in the granules which it contains; and according to a fourth, it lies in the ground-substance in which these granules are embedded. One view holds this ground substance to be homogeneous, another regards it as possessing a fine foam-structure. It may at present be regarded as

not of sense-substances only, but of living substance generally. Each cell has its specific energy in Johannes Müller's sense, and in its extended form there is no more general law for all the operations of stimuli than this law of specific energy. To take examples, whether a muscle be stimulated by a chemical, mechanical, thermal or electrical stimulus the result is in each case the same—namely, a twitching of the muscle. Let a salivary gland be stimulated chemically, mechanically, electrically or in any other way, there always follows the same specific action—a secretion of saliva; no matter what be the kind of stimulus acting upon it, the liver-cell always reacts by producing bile, and so on. On the other hand, one and the same stimulus—the electric current, for example—gives in each form of living substance a specific result: twitching in the muscle, secretion of saliva in the salivary gland, production of bile in the liver-cell, &c. That is, of course, with the proviso that the effect of the stimulus be exciting and not depressing. The following general formulation, however, of the law of specific energy brings the depressing stimuli also within its scope: "Different stimuli produce in each form of living substance an increase or a diminution of its specific activity." As already observed, it will probably be found that those weak chronic forms of stimulation which produce qualitative changes may also be comprised under this general law.

Mechanism of Life.

The knowledge thus far acquired from analysis of vital phenomena and their changes under the influence of stimuli affords but a very indefinite temporary basis for the theory of the actual vital process itself, of which vital phenomena are the outward manifestation. The conceptions to which physiological research has hitherto attained in this matter are of a more or less doubtful nature. The facts contained in them still require to be linked together by hypotheses if we are to obtain even a vague outline of what lies hidden behind the great riddle of life. Such hypotheses, serving as they do to link facts consistently together, are absolutely essential, however, to the further progress of research, and without their aid any systematic investigation would be impracticable. But at the same time it must never be forgotten that these hypotheses are merely provisional, and that whenever they are found to be no longer in harmony with the widening range of new experiences and ideas they must either be proved to be facts or be subjected to modification. This is the point of view from which we must deal with modern ideas concerning the nature of the actual vital process—the mechanism of life.

Metabolism.

The fundamental fact of life is the metabolism of living substance which is continually and spontaneously undergoing decomposition, and building itself up anew with the help of the food-substances it takes in. These processes of decomposition and of reconstruction may be briefly designated as *dissimilation* (catabolism) and *assimilation* (anabolism) respectively. Now the question arises: How are we to understand this process of dissimilation and assimilation from a mechanical standpoint? It is quite evident that we have to do with some chemical occurrence; but *how* are the chemical transformations brought about? There are obviously two possibilities. It is conceivable that the decomposition of food-stuffs and the formation of excretion-products in the cell-body are caused by the repeated casual encounter of a great series of chemical combinations and by their repeatedly reacting upon one another in the same manner, bringing about transformations and forming waste products which are excreted, while at the same time certain chemical affinities are always taking in from without new chemical combinations (food-stuffs) and uniting them. This theory was in fact occasionally advanced in former times, particularly in its chemical aspect, and the belief was especially entertained that the enzymes in living substance might play an important part in these transformations. This assumption, however, leads to no clear and lucid image of what takes place, and, moreover, draws too largely upon auxiliary hypotheses. It has therefore met with but little acceptance. The other possible explanation of metabolism is that its whole process is confined to one single class of chemical combinations whose tendency it is to be constantly undergoing spontaneous decomposition and regeneration. This latter theory was founded by Ludimar Hermann (b. 1838), Eduard Friedrich Pflüger (b. 1829) and others, and has met with universal recognition because of its naturalness, simplicity and clearness.

Proteids.

Starting with this hypothesis, the path of further research lies clear and well defined before us. In the first place, we are obviously met by the question: What conception are we to form of these combinations on which hinges the whole vital process? Among the organic matters which compose living substance, proteids perform the most important part. Proteids and proteid-compounds form the only organic matter which is never absent from any cell. They form also the greater part of all the organic compounds of the cell, unless reserve-stuffs are accumulated to a considerable extent, and they are by far the most complicated of the compounds of living substance. While animal life is impossible without proteid food, there are, on the other hand, animals which can continue to subsist on proteid alone. This series of facts proves very conclusively that proteids and their compounds play by far the most important part of all organic matter in the processes of life. The idea thus naturally presents itself that the required hypothetical compound forming the central point of metabolism will be found to bear a very close relation to proteids. But another point must be here considered. The proteids and their compounds known to us are, comparatively speaking, stable compounds, which never undergo spontaneous decomposition so long as they are protected from outward injury, whereas the hypothetical combination which lies at the centre of organic metabolism is extraordinarily labile and continually undergoing spontaneous decomposition. Therefore we have to think not of ordinary proteids in this case, but of still more complicated combinations, the atoms in the molecule of which have a strong tendency to group themselves in new arrangements. Owing to their fundamental importance, these combinations have been termed "biogens." When we come to inquire how such labile biogen molecules are built up out of the proteids of food, we find our knowledge very much restricted. Doubtless the intramolecular addition of inspired oxygen has much to do with it; for living substance when deprived of oxygen loses its irritability—that is to say, its tendency to decomposition. The fact that the decomposition of living substance is always associated with the formation of carbonic acid—a circumstance obviously necessitating the aid of oxygen—also points to the absolute indispensableness of oxygen in the matter. Pflüger has further suggested that the molecule of living substance owes its lability and its tendency to form carbonic acid when joined by oxygen atoms principally to cyanogen groups which are contained in it. According to this view, the following is supposed to be the process of the formation of biogen molecules: It is assumed that the biogen molecules already present in living substance take out of the proteids of food certain groups of atoms, and dispose them so as to produce cyanogen-like compounds. The addition of oxygen atoms then brings the biogen molecule to the maximum of its power of decomposition, so that—partly spontaneously, but more especially when impelled by a stimulus—it breaks down somewhat explosively, causing the formation of carbonic acid. In this proceeding, according to the hypothesis which is the most widely accepted and the most fruitful in results, would lie the very germ of the vital process.

Mechanism of Cell-life.

If we accept these views as far as their general principle is concerned, assimilation is the re-formation of biogen molecules by those already existing, aided by food-stuffs; dissimilation, the decomposition of biogen molecules. To this primary process, however, is attached a whole series of secondary chemical processes, which serve partly to work upon the food so as to fit it for the building up of biogen molecules, and partly to form out of the direct decomposition-products of the biogen molecules the characteristic secretion-products of living substance (excretions and secretions). The various workings of matter in the cell are rendered very much more

complex by the circumstance that the living cell exhibits various morphological differentiations—above all, the differentiation in protoplasm and nucleus. Again, a transformation of energy is inseparably connected with metabolism. Along with food and oxygen potential chemical energy is continually being introduced into the cell, to be accumulated in the biogen molecules, and at their decomposition transformed into kinetic energy, which finds an outlet in the various manifestations of energy in the cell—motion, heat, and so forth. In the light of this hypothesis the operations of stimuli also become comprehensible. Seeing that there is an initial tendency to the occurrence of certain definite chemical processes, which are associated with the reconstruction and decomposition of biogen molecules, various stimuli will either further or hinder the course of this metabolic series. A cell which is exposed to no outward disturbance, and which continues always in the unvarying medium provided by an exact sufficiency of food, will be in "metabolic equilibrium"—that is to say, its assimilation and its dissimilation will be equal (A=D). When, however, the influence of external stimuli is brought to bear upon them—that is to say, any change in their environing vital conditions—A and D will either be altered in similar proportion, or their mutual equilibrium will be disturbed. In the former case the vital processes will merely be intensified in their course; in the latter and usual case the result will be determined according to the part of metabolism excited or depressed. When the effect of a stimulus is to excite D continuously in a high degree without correspondingly increasing A, the result is a dying off—an atrophy. In the contrary case, when A remains continuously greater than D, the result is growth, increase and reproduction of the cell. Experience proves, however, that A and D stand in a certain relation of mutual dependence to each other, with the result that when D has been increased by a stimulus, for example, A correspondingly increases during the stimulation, and continues to do so after its cessation, till the loss in living substance produced by the stimulation of D is eventually made good, and metabolic equilibrium is restored. The muscle may be taken as an example of this self-regulation of metabolism common to all living substance (Hering's *Selbststeuerung des Stoffwechsels*). When a muscle has been fatigued by some stimulation causing an enormous increase of D, there is a corresponding spontaneous increase in A. After some time the muscle is observed to have recovered. It has once more become capable of performing work; its metabolism is again in equilibrium.

Metabolic Equilibrium.

The vital phenomena of the cell may be derived mechanically from metabolism and the changes it undergoes under the influence of stimuli. Our ability to do this will increase more rapidly as we become better acquainted with the details of the metabolism of the cell itself. The foregoing outline must be regarded, of course, as embodying only a fragmentary hypothesis, which can serve as a guide for further research only so long as it does not clash with facts, and which must be amplified, specialized and developed with the widening of specific knowledge regarding the cell's metabolism. The relations already known are so exceedingly complex that only by slow degrees can we pursue the investigation of separate fragments of the entire metabolic series. The differentiation of nucleus and protoplasm in the living substance of the cell alone gives rise to an extraordinary complication in the metabolic process, for these two parts of the cell stand in the most complicated correlation with one another as well as with the environing medium—a fact of which the experiments made by vivisection in various free-living cell-forms have furnished abundant evidence. The farther such knowledge advances, the more rounded, clear and free from hypotheses will become our conception of the cell's metabolism. But the cell is the elementary component part of all organisms, and from the life of individual cells is constructed the life of the separate tissues and various organs, and thus of the entire organism. Hence the cell is the only vital element which the organism possesses, and therefore the investigation of the vital processes in its separate cells leads ultimately to a knowledge regarding the mechanism of life in the whole.

Cell-Processes the Secret of Life.

Vegetable physiology is dealt with in the article PLANTS: *Physiology*. For details of different parts of the animal body, see ANIMAL HEAT; RESPIRATORY SYSTEM; VASCULAR SYSTEM; TOUCH; SMELL; TASTE; VISION; HEARING; VOICE; MUSCLE AND NERVE; SLEEP; HYPNOTISM; BRAIN; SPINAL CORD; SYMPATHETIC SYSTEM; BLOOD; LYMPH; PHAGOCYTOSIS; DIGESTIVE ORGANS; NUTRITION, &c.

The principal modern English textbooks of animal physiology are those of Sir Michael Foster (1885), A. E. Schäfer (1898), Noël Paton (1908), Halliburton (1909), and Starling (1909). See, however, the bibliographical notes to the separate articles. (M.V.)

PIACENZA (Lat. *Placentia*), a town and episcopal see of Emilia, Italy, the capital of the province of Piacenza, 42½ m. S.E. of Milan and 91 m. N.W. of Bologna by rail. Pop. (1906), 39,786. It lies on the Lombard plain, 217 ft. above sea-level, near the right bank of the Po, which here is crossed by road and railway bridges, just below the confluence of the Trebia. It is still surrounded by walls with bastions and fosse in a circuit of 4 m. The cathedral was erected between 1122 and 1233, in the Lombard Romanesque style, under the direction of Santo da Sambuceto, on the site of a church of the 9th century which had been destroyed by earthquake. The west front has three doors with curious pillared porches. The campanile is a massive square brick tower 223 ft. high; the iron cage attached to one of its windows was put up in 1495 by Ludovico il Moro for the confinement of persons guilty of treason or sacrilege. The crypt is a large church supported by one hundred columns. The entire edifice has been restored since 1898, and the frescoes by Guercino and Caracci, which decorate parts of its roof, though good in themselves, are inappropriate to its severe style. Sant' Antonino, which was the cathedral church till 877, is supposed to have been founded by St Victor, the first bishop of Piacenza, in the 4th century, and restored in 903; it was rebuilt in 1104, and altered in 1857. It was within its walls that the deputies of the Lombard League swore to the conditions of peace ratified in 1183 at Constance. The Gothic brick vestibule (Il Paradiso) on the north side is one of the older parts of the building. San Francesco, a spacious Gothic edifice begun by the Franciscans in 1278, was erected on the site of the palace of Ubertino Landi, a leader of the Ghibelline party. S. Savino, a fine Romanesque building of A.D. 903 (well restored in 1903), contains a mosaic pavement of this period with curious representations, including one of a game of chess. S. Sisto, which dates from 1499, and takes the place of the church founded in 874 by Angilberga (consort of the emperor Louis II.), lost its chief attraction when Raphael's Sistine Madonna (now in Dresden) was sold by the monks in 1754 to Frederick Augustus III. Its place, however, is occupied by a copy by Avanzini, and there are also several good intarsias by Bartolomeo da Busseto. S. Sepolcro and S. Maria della Campagna are both good early Renaissance churches; the latter is rich in frescoes by Pordenone. S. Anna, dating from 1334, was the church of the barefooted Carmelites. Of the secular buildings the most interesting is the Palazzo Communale, begun in 1281, one of the finest buildings of its kind in Italy. The square in front is known as the Piazza dei Cavalli, from the two bronze equestrian statues of Ranuccio (1620) and his father Alexander, prince of Parma, governor of the Netherlands (1625). Both were designed by Francesco Mocchi. The Palazzo dei Tribunali and the Palazzo degli Scoti are fine early Renaissance brick buildings with terra-cotta decorations. The huge Farnese palace was begun after Vignola's designs by Margaret of Austria in 1558, but it was never completed, and since 1800 it has been used as barracks. Other buildings or institutions of note are the old and the new bishop's palaces, the fine theatre designed by Lotario Tomba in 1803, the great hospital dating from 1471, the library presented to the commune in 1846 by the marquis Ferdinando Landi, and the Passerini library founded in 1685. The Museo Civico, formed in 1903, contains collections of antiquities (though many of the Roman antiquities of Piacenza have passed to the museum of Parma), some good Flemish tapestries and a few pictures. The castle erected by Antonio da Sangallo the younger has been demolished. Piacenza is the junction of the Milan and Bologna line with that from Voghera and Turin. From Codogno, 7 m.

to the north, a branch line runs to Cremona. By road Piacenza is 88 m. north-east of Genoa. The town has an arsenal, a technical and arts school, and various industries—iron and brass works, foundries, silk-throwing, printing works and flour-mills.

Piacenza was made a Roman colony in 218 B.C. While its walls were yet unfinished it had to repulse an attack by the Gauls, and in the latter part of 218 it afforded protection to the remains of the Roman army under Scipio which had been defeated in the great battle on the Trebia. In 205 it withstood a protracted siege by Hasdrubal. Five years later the Gauls burned the city; and in 190 it had to be recruited with three thousand families. In 187 it was connected with Ariminum and the south by the construction of the Via Aemilia. Later on it became a very important road centre; the continuation northwards of the Via Aemilia towards Milan, with a branch to Ticinum, crossed the Po there, and the Via Postumia from Cremona to Dertona and Genoa passed through it. Later still Augustus reconstructed the road from Dertona to Vada, and into Gallia Narbonensis, and gave it the name of Julia Augusta from Placentia onwards. The rectangular arrangement of the streets in the centre of the town, through which passes the Via Aemilia, is no doubt a survival from Roman times. Placentia is mentioned in connexion with its capture by Cinna and a defeat of the forces of Carbo in the neighbourhood (82 B.C.), a mutiny of Julius Caesar's garrison (50 B.C.), another mutiny under Augustus (40 B.C.), the defence of the city by Spurinna, Otho's general, against Caecina, Vitellius's general (A.D. 69), and the defeat of Aurelian by the Marcomanni outside the walls (A.D. 271). In 546 Totila reduced Piacenza by famine. Between 997 and 1035 the city was governed by its bishops, who had received the title of count from Otho III. At Roncaglia, 5 m. to the east, the emperor Conrad II. held the diet which passed the Salic law. In the latter part of the 12th century it was one of the leading members of the Lombard League. For the most part it remained Guelph, though at times, as when it called in Galeazzo Visconti, it was glad to appeal to a powerful Ghibelline for aid against its domestic tyrants. In 1447 the city was captured and sacked by Francesco Sforza. Having been occupied by the papal forces in 1512, it was in 1545 united with Parma (*q.v.*) to form an hereditary duchy for Pierluigi Farnese, son of Paul III. In 1746 a battle between the Franco-Spanish forces and the Austrians was fought under the city walls, and in 1796 it was occupied by the French. In 1848 Piacenza was the first of the towns of Lombardy to join Piedmont; but it was reoccupied by the Austrians till 1859.

PIANOFORTE (Ital. *piano*, soft, and *forte*, loud). The group of keyed stringed musical instruments, among which the pianoforte is latest in order of time, has been invented and step by step developed with the modern art of music, which is based upon the simultaneous employment of different musical sounds. In the 10th century the "organum" arose, an elementary system of accompaniment to the voice, consisting of fourths and octaves below the melody and moving with it; and the organ (*q.v.*), the earliest keyed instrument, was, in the first instance, the rude embodiment of this idea and convenient means for its expression. There was as yet no keyboard of balanced key levers; sliders were drawn out like modern draw-stops, to admit the compressed air necessary to make the pipes sound. About the same time arose a large stringed instrument, the organistrum,[1] the parent of the now obsolete hurdy-gurdy; as the organ needed a blower as well as an organist, so the player of the organistrum required a handle-turner, by whose aid the three strings of the instrument were made to sound simultaneously upon a wheel, and, according to the well-known sculptured relief of St George de Boscherville, one string was manipulated by means of a row of stoppers or tangents pressed inwards to produce the notes. The other strings were drones, analogous to the drones of the bagpipes, but originally the three strings followed the changing organum.

History of Evolution.

In the 11th century, the epoch of Guido d'Arezzo, to whom the beginning of musical notation is attributed, the Pythagorean monochord, with its shifting bridge, was used in the singing schools to teach the intervals of the plain-song of the church. The practical necessity, not merely of demonstrating the proportionate relations of the intervals, but also of initiating pupils into the different gradations of the church tones, had soon after Guido's time brought into use quadruplex-fashioned monochords, which were constructed with scales, analogous to the modern practice with thermometers which are made to show both Réaumur and Centigrade, so that four lines indicated as many authentic and as many plagal tones. This arrangement found great acceptance, for Aribo,[2] writing about fifty years after Guido, says that few monochords were to be found without it. Had the clavichord then been known, this makeshift contrivance would not have been used. Aribo strenuously endeavoured to improve it, and "by the grace of God" invented a monochord measure which, on account of the rapidity of the leaps he could make with it, he named a wild-goat (*caprea*). Jean de Muris (*Musica speculativa*, 1323) teaches how true relations may be found by a single-string monochord, but recommends a four-stringed one, properly a tetrachord, to gain a knowledge of unfamiliar intervals. He describes the musical instruments known in his time, but does not mention the clavichord or monochord with keys, which could not have been then invented. Perhaps one of the earliest forms of such an instrument, in which stoppers or tangents had been adopted from the organistrum, is shown in fig. 1, from a wood carving of a vicar choral or organist, preserved in St Mary's church, Shrewsbury. The latest date to which this interesting figure may be attributed is 1460, but the conventional representation shows that the instrument was then already of a past fashion, although perhaps still retained in use and familiar to the carver.

Monochord; Clavichord.

FIG. 1.—Earliest existing representation of a Keyed Stringed Instrument, from St Mary's, Shrewsbury (primitive Clavichord). Before 1460.

In the Weimar *Wunderbuch*,[3] a MS. dated 1440, with pen and ink miniatures, is given a "clavichordium" having 8 short and apparently 16 long keys; the artist has drawn 12 strings in a rectangular case, but no tangents are visible. A keyboard of balanced keys existed in the little portable organ known as the regal, so often represented in old carvings, paintings and stained windows. Vitruvius, *De architectura*, lib. x. cap. xi., translated by Newton, describes a balanced keyboard; but the key apparatus is more particularly shown in *The Pneumatics of Hero of Alexandria*, translated by Bennet Woodcroft (London, 1851). In confirmation of this has been the remarkable recovery at Carthage[4] of a terra-cotta model of a Hydraulikon or water organ, dating from the 2nd century A.D., in which a balanced keyboard of 18 or 19 keys is shown. It seems likely the balanced keyboard was lost, and afterwards reinvented. The name of

[1] An organistrum is shown in the lower right-hand corner of the full page miniature of a fine 12th-century psalter of English workmanship, forming part of the Hunterian collection in University Court Library, Glasgow. No. 31 in *Catalogue of the Exhibition of Illuminated MSS. at the Burlington Fine Arts Club* (1908).

[3] *Grossherzogliche Bibliothek*. See also Dr Alwin Schulz, *Deutsches Leben im xiv. and xv. Jahrhund.* (Vienna, 1892), p. 518, fig. 522.

[4] For an illustration of this important piece of evidence, see under ORGAN: *Ancient History*; and for description and illustration of balanced keys, see KEYBOARD.

regal was derived from the rule (*regula*) or graduated scale of keys, and its use was to give the singers in religious processions the note or pitch. The only instrument of this kind known to exist in the United Kingdom is at Blair Atholl, and it bears the very late date of 1630. The Brussels regal [1] may be as modern. These are instances of how long a some-time admired musical instrument may remain in use after its first intention is forgotten. We attribute the adaptation of the narrow regal keyboard to what was still called the monochord, but was now a complex of monochords over one resonance board, to the latter half of the 14th century; it was accomplished by the substitution of tangents fixed in the further ends of the balanced keys for the movable bridges of the monochord or such stoppers as are shown in the Shrewsbury carving. Thus the monochordium or "payre of monochordis" became the clavichordium or "payre of clavichordis"—pair being applied, in the old sense of a "pair of steps," to a series of degrees. This use of the word to imply gradation was common in England to all keyed instruments; thus we read, in the Tudor period and later, of a pair of regals, organs, or virginals. Ed. van der Straten [2] reproduces a so-called clavichord of the 15th century from a MS. in the public library at Ghent. The treatise is anonymous, but other treatises in the same MS. bear dates 1503 and 1504. Van der Straeten is of opinion that the drawing may be assigned to the middle of the 15th century. The scribe calls the instrument a clavicimbalum, and this is undoubtedly correct; the 8 strings in the drawing are stretched from back to front over a long soundboard, the longest strings to the left; 8 keys, 4 long and 4 short with levers to which are attached the jacks, are seen in a horizontal line behind the keyboard, and behind them again are given the names of the notes a, b, c, d, e, f, g, h. In the Weimar *Wunderbuch* is a pen-and-ink sketch of the "clavicimbalum" [3] placed upon a table, in which we recognize the familiar outline of the harpsichord, but on a smaller scale. The keyboard shows white and black notes—the latter short keys, one between each group of two white keys, precisely as in the instrument reproduced by Van der Straeten—but no mechanism is visible under the strings.

The earliest known record of the clavichord occurs in some rules of the minnesingers,[4] dated 1404, preserved at Vienna. The monochord is named with it, showing a differentiation of these instruments, and of them from the clavicymbalum, the keyed cymbal, cembalo (Italian), or psaltery. From this we learn that a keyboard had been thus early adapted to that favourite medieval stringed instrument, the "cembalo" of Boccaccio, the "sautrie" of Chaucer. There were two forms of the psaltery: (1) the trapeze, one of the oldest representations of which is to be found in Orcagna's famous Trionfo della Morte in the Campo Santo at Pisa, and another by the same painter in the National Gallery, London; and (2) the contemporary "testa di porco," the pig's head, which was of triangular shape as the name suggests. The trapeze psaltery was strung horizontally, the "istromento di porco" either horizontally or vertically—the notes, as in the common dulcimer, being in groups of three or four unisons. In these differences of form and stringing we see the cause of the ultimate differentiation of the spinet and harpsichord. The compass of the psalteries was nearly that of Guido's scale; but according to Mersenne,[5] the lowest interval was a fourth, G to C, which is worthy of notice as anticipating the later "short measure" [6] of the spinet and organ.

The simplicity of the clavichord inclines us to place it, in order of time, before the clavicymbalum or clavicembalo; but we do not know how the sounds of the latter were at first excited. There is an indication as to its early form to be seen in the church of the Certosa near Pavia, which compares in probable date with the Shrewsbury example. We quote the reference to it from Dr Ambros.[7] He says a carving represents King David as holding an "istromento di porco" which has eight strings and as many keys lying parallel to them; inside the body of the instrument, which is open at the side nearest the right hand of King David, he touches the keys with the right hand and damps the strings with the left. The attribution of archaism applies with equal force to this carving as to the Shrewsbury one, for when the monastery of Certosa near Pavia was built by Ambrogio Fossana in 1472, chromatic keyboards, which imply a considerable advance, were already in use. There is an authentic representation of a chromatic keyboard, painted not later than 1426, in the St Cecilia panel (now at Berlin) of the famous Adoration of the Lamb by the Van Eycks. The instrument depicted is a positive

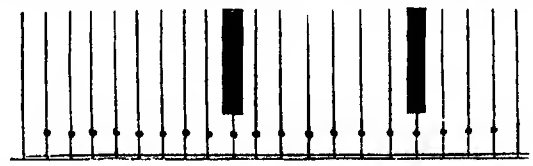

FIG. 2.—Diatonic Clavichord Keyboard (Guido's Scale) from Virdung. Before 1511.

organ, and it is interesting to notice in this realistic painting that the keys are evidently boxwood, as in the Italian spinets of later date, and that the angel plays a common chord—A with the right hand, F and C with the left. But diatonic organs with eight steps or keys in the octave, which included the B flat and the B natural, as in Guido's scale, were long preserved, for Praetorius speaks of them as still existing nearly two hundred years later. This diatonic keyboard, we learn from Sebastian Virdung (*Musica getutscht und auszgezogen*, Basel, 1511), was the keyboard of the early clavichord. We reproduce his diagram as the only authority we have for the disposition of the one short key.

The extent of this scale is exactly Guido's. Virdung's diagram of the chromatic is the same as our own familiar keyboard, and comprises three octaves and a note, from F below the bass stave to G above the treble. But Virdung tells us that even then clavichords were made longer than four octaves by repetition of the same order of keys. The introduction of the chromatic order he attributes to the study of Boetius, and the consequent endeavour to restore the three musical *genera* of the Greeks—the diatonic, chromatic and enharmonic. But the last-named had not been attained. Virdung gives woodcuts of the clavichordium, the virginal, the clavicymbalum and the clavicytherium. We reproduce three of them (figs. 3, 6 and 12), omitting the virginal

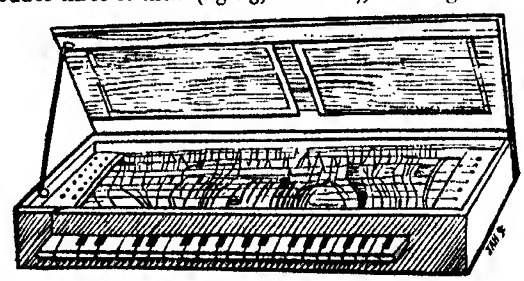

FIG. 3.—Virdung's Clavichordium, 1511; reversed facsimile.

as obviously incorrect. Writers on musical instruments have continually repeated these drawings without discerning that in the printing they are reversed, which puts the keyboards entirely wrong, and that in Luscinius's Latin translation of Virdung (*Musurgia, sive praxis musicae*, Strasburg, 1536), which has been hitherto chiefly followed, two of the engravings, the clavicimbalum and the clavicytherium, are transposed, another cause of error. Martin Agricola (*Musica instrumentalis*, Wittenberg, 1529) has copied Virdung's illustrations with some differences of perspective, and the addition, here and there, of errors of his own.

[7] *Geschichte der Musik*, ii. 544–555.

Still vulgarly known as monochord, Virdung's clavichord was really a box of monochords, all the strings being of the same length. He derives the clavichord from Guido's monochord as he does the virginal from the psaltery, but, at the same time, confesses he does not know when, or by whom, either instrument was invented. We observe in this drawing the short sound-board, which always remained a peculiarity of the clavichord, and the straight sound-board bridge—necessarily so when all the strings were of one length. To gain an angle of incidence for the tangents against the strings the keys were made crooked, an expedient further rendered necessary by the "fretting"—three tangents, according to Virdung, being directed to stop as many notes from each single group of three strings tuned in unison; each tangent thus made a different vibrating length of string. In the drawing the strings are merely indicated. The German for fret is *Bund*, and such a clavichord, in that language, is known as a "gebundenes Clavichord," both fret (to rub) and *Bund* (from *binden*, to bind) having been taken over from the lute or viol. The French and Italians employ "touche" and "tasto," touch. Praetorius, who wrote a hundred years later than Virdung, says two, three and four tangents were thus employed in stopping. There are extant small clavichords having three keys and tangents to one pair of strings, and others have no more than two tangents to a note formed by a pair of strings, instead of three. Thus seven pairs of strings suffice for an octave of twelve keys, the open notes being F, G, A, B flat, C, D, E flat, and by an unexplained peculiarity, perhaps derived from some special estimation of the notes which were connected with the church modes, A and D are left throughout free from a second tangent. A corresponding value of these notes is shown by their independence of chromatic alteration in tuning the double Irish harp, as explained by Vincentio Galilei in his treatise on music (*Dialogo della musica*, Florence, 1581). Adlung, who died in 1762, speaks of another fretting, but it must have been an adaptation to the modern major scale, the "free" notes being E and B. Clavichords were made with double fretting up to about the year 1700—that is to say, to the epoch of J. S. Bach, who, taking advantage of its abolition and the consequent use of independent pairs of strings for each note, was enabled to tune in all keys equally, which had been impossible so long as the fretting was maintained. The modern scales having become established, Bach was now able to produce, in 1722, *Das wohltemperirte Clavier*, the first collection of preludes and fugues in all the twenty-four major and minor scales for a clavichord which was tuned, as to concordance and dissonance, fairly equal.

The oldest clavichord, here called manicordo (as French *manicorde*, from monochord), known to exist is that shown in fig. 4. It will be observed that the lowest octave is here already

FIG. 4.—Manicordo (Clavichord) d'Eleonora di Montalvo, 1659; Kraus Museum, Florence.

"bundfrei" or fret-free. The strings are no longer of equal length, and there are three bridges, divisions of the one bridge, in different positions on the sound-board. Mersenne's "manicorde" (*Harmonie universelle*, Paris, 1636, p. 115), shown in an engraving in that work, has the strings still nearly of equal length, but the sound-board bridge is divided into five. The fretted clavichords made in Germany in the last years of the 17th century have the curved sound-board bridge, like a spinet. In the clavichord the tangents always form the second bridge, indispensable for the vibration, besides acting as the sound exciters (fig. 5). The common damper to all the strings is a list of cloth, interwoven behind the tangents. As the tangents quitted the strings the cloth immediately stopped all vibration. Too much cloth would diminish the tone of this already feeble instrument, which gained the name of "dumb spinet" from its use. In the clavichord in Rubens's St Cecilia (Dresden Gallery)—interesting as perhaps representing that painter's own instrument—the damping cloth is accurately painted. The number of keys

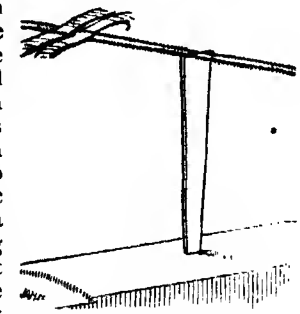

FIG. 5.—Clavichord Tangent.

there shown is three octaves and a third, F to A—the same extent as in Handel's clavichord now in the museum at Maidstone (an Italian instrument dated 1726, and not fretted), but with the peculiarity of a combined chromatic and short octave in the lowest notes, to which we shall have to refer when we arrive at the spinet; we pass it by as the only instance we have come across in the clavichord.

The clavichord must have gone out of favour in Great Britain and the Netherlands early in the 16th century, before its expressive power, which is of the most tender and intimate quality, could have been, from the nature of the music played, observed—the more brilliant and elegant spinet being preferred to it. Like the other keyboard instruments it had no German name, and can hardly have been of German origin. Holbein, in his drawing of the family of Sir Thomas More, 1528, now at Basel, indicates the place for "Klavikordi und ander Seytinspill." But it remained longest in use in Germany—until even the beginning of the 19th century. It was the favourite "Klavier" of the Bachs. Besides that of Handel already noticed, there are in existence clavichords the former possession of which is attributed to Mozart and Beethoven. The clavichord was obedient to a peculiarity of touch possible on no other keyboard instrument. This is described by C. P. Emmanuel Bach in his famous essay on playing and accompaniment, entitled *Versuch über die wahre Art das Klavier zu spielen* ("An Essay on the True Way to play Keyboard Instruments.") It is the *Bebung* (trembling), a vibration in a melody note of the same nature as the tremolo frequently employed by violin players to heighten the expressive effect; it was gained by a repeated movement of the fleshy end of the finger while the key was still held down. The *Bebung* was indicated in the notation by dots over the note to be affected by it, perhaps showing how many times the note should be repeated. According to the practice of the Bachs, as handed down to us in the above mentioned essay, great smoothness of touch was required to play the clavichord in tune. As with the monochord, the means taken to produce the sound disturbed the accuracy of the string measurement by increasing tension, so that a key touched too firmly in the clavichord, by unduly raising the string, sharpened the pitch, an error in playing deprecated by C. P. Emmanuel Bach. This answers the assertion which has been made that J. S. Bach could not have been nice about tuning when he played from preference on an instrument of uncertain intonation.

Virginal.

The next instrument described by Virdung is the virginal (*virginalis*, proper for a girl), a parallelogram in shape, having the same projecting keyboard and compass of keys the same as the clavichordium. Here we can trace derivation from the psaltery in the sound-board covering the entire inner surface of the instrument and in the triangular disposition of the strings. The virginal in Virdung's drawing has an impossible position with reference to the keyboard, which renders its reproduction as an illustration useless. But in the next drawing, the clavi-

Clavicimbalum.

cimbalum, this is rectified, and the drawing, reversed on account of the keyboard, can be accepted as roughly representing the instrument so called (fig. 6). There would be

regal was derived from the rule (*regula*) or graduated scale of keys, and its use was to give the singers in religious processions the note or pitch. The only instrument of this kind known to exist in the United Kingdom is at Blair Atholl, and it bears the very late date of 1630. The Brussels regal[1] may be as modern. These are instances of how long a some-time admired musical instrument may remain in use after its first intention is forgotten. We attribute the adaptation of the narrow regal keyboard to what was still called the monochord, but was now a complex of monochords over one resonance board, to the latter half of the 14th century; it was accomplished by the substitution of tangents fixed in the further ends of the balanced keys for the movable bridges of the monochord or such stoppers as are shown in the Shrewsbury carving. Thus the monochordium or "payre of monochordis" became the clavichordium or "payre of clavichordis"—pair being applied, in the old sense of a "pair of steps," to a series of degrees. This use of the word to imply gradation was common in England to all keyed instruments; thus we read, in the Tudor period and later, of a pair of regals, organs, or virginals. Ed. van der Straten[2] reproduces a so-called clavichord of the 15th century from a MS. in the public library at Ghent. The treatise is anonymous, but other treatises in the same MS. bear dates 1503 and 1504. Van der Straeten is of opinion that the drawing may be assigned to the middle of the 15th century. The scribe calls the instrument a clavicimbalum, and this is undoubtedly correct; the 8 strings in the drawing are stretched from back to front over a long soundboard, the longest strings to the left; 8 keys, 4 long and 4 short with levers to which are attached the jacks, are seen in a horizontal line behind the keyboard, and behind them again are given the names of the notes a, b, c, d, e, f, g, h. In the Weimar *Wunderbuch* is a pen-and-ink sketch of the "clavicimbalum"[3] placed upon a table, in which we recognize the familiar outline of the harpsichord, but on a smaller scale. The keyboard shows white and black notes—the latter short keys, one between each group of two white keys, precisely as in the instrument reproduced by Van der Straeten—but no mechanism is visible under the strings.

The earliest known record of the clavichord occurs in some rules of the minnesingers,[4] dated 1404, preserved at Vienna. The monochord is named with it, showing a differentiation of these instruments, and of them from the clavicymbalum, the keyed cymbal, cembalo (Italian), or psaltery. From this we learn that a keyboard had been thus early adapted to that favourite medieval stringed instrument, the "cembalo" of Boccaccio, the "sautrie" of Chaucer. There were two forms of the psaltery: (1) the trapeze, one of the oldest representations of which is to be found in Orcagna's famous Trionfo della Morte in the Campo Santo at Pisa, and another by the same painter in the National Gallery, London; and (2) the contemporary "testa di porco," the pig's head, which was of triangular shape as the name suggests. The trapeze psaltery was strung horizontally, the "istromento di porco" either horizontally or vertically—the notes, as in the common dulcimer, being in groups of three or four unisons. In these differences of form and stringing we see the cause of the ultimate differentiation of the spinet and harpsichord. The compass of the psalteries was nearly that of Guido's scale; but according to Mersenne,[5] the lowest interval was a fourth, G to C, which is worthy of notice as anticipating the later "short measure"[6] of the spinet and organ.

The simplicity of the clavichord inclines us to place it, in order of time, before the clavicymbalum or clavicembalo; but we do not know how the sounds of the latter were at first excited. There is an indication as to its early form to be seen in the church of the Certosa near Pavia, which compares in probable date with the Shrewsbury example. We quote the reference to it from Dr Ambros.[7] He says a carving represents King David as holding an "istromento di porco" which has eight strings and as many keys lying parallel to them; inside the body of the instrument, which is open at the side nearest the right hand of King David, he touches the keys with the right hand and damps the strings with the left. The attribution of archaism applies with equal force to this carving as to the Shrewsbury one, for when the monastery of Certosa near Pavia was built by Ambrogio Fossana in 1472, chromatic keyboards, which imply a considerable advance, were already in use. There is an authentic representation of a chromatic keyboard, painted not later than 1426, in the St Cecilia panel (now at Berlin) of the famous Adoration of the Lamb by the Van Eycks. The instrument depicted is a positive

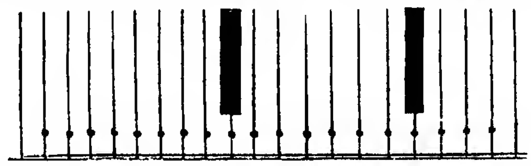

FIG. 2.—Diatonic Clavichord Keyboard (Guido's Scale) from Virdung. Before 1511.

organ, and it is interesting to notice in this realistic painting that the keys are evidently boxwood, as in the Italian spinets of later date, and that the angel plays a common chord—A with the right hand, F and C with the left. But diatonic organs with eight steps or keys in the octave, which included the B flat and the B natural, as in Guido's scale, were long preserved, for Praetorius speaks of them as still existing nearly two hundred years later. This diatonic keyboard, we learn from Sebastian Virdung (*Musica getutscht und auszgezogen*, Basel, 1511), was the keyboard of the early clavichord. We reproduce his diagram as the only authority we have for the disposition of the one short key.

The extent of this scale is exactly Guido's. Virdung's diagram of the chromatic is the same as our own familiar keyboard, and comprises three octaves and a note, from F below the bass stave to G above the treble. But Virdung tells us that even then clavichords were made longer than four octaves by repetition of the same order of keys. The introduction of the chromatic order he attributes to the study of Boetius, and the consequent endeavour to restore the three musical *genera* of the Greeks—the diatonic, chromatic and enharmonic. But the last-named had not been attained. Virdung gives woodcuts of the clavichordium, the virginal, the clavicymbalum and the clavicytherium. We reproduce three of them (figs. 3, 6 and 12), omitting the virginal

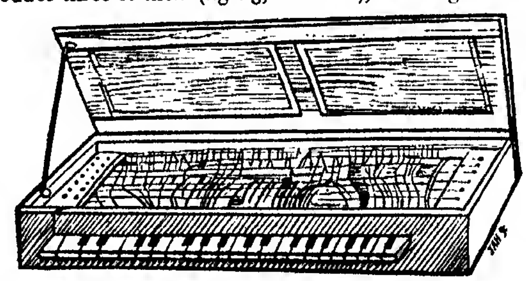

FIG. 3.—Virdung's Clavichordium, 1511; reversed facsimile.

as obviously incorrect. Writers on musical instruments have continually repeated these drawings without discerning that in the printing they are reversed, which puts the keyboards entirely wrong, and that in Luscinius's Latin translation of Virdung (*Musurgia, sive praxis musicae*, Strasburg, 1536), which has been hitherto chiefly followed, two of the engravings, the clavicimbalum and the clavicytherium, are transposed, another cause of error. Martin Agricola (*Musica instrumentalis*, Wittenberg, 1529) has copied Virdung's illustrations with some differences of perspective, and the addition, here and there, of errors of his own.

the rectangular instrument in Italy is "spinetta tavola." In England, from Henry VII. to Charles II., all quilled instruments (*stromenti di penna*), without distinction as to form, were known as virginals. It was a common name, equivalent to the contemporary Italian *clavicordo* and Flemish *clavisingel*. From the latter, by apocope, we arrive at the French *clavecin*—the French *clavier* (*clavis*, a key), a keyboard, being in its turn adopted by the Germans to denote any keyboard stringed instrument.

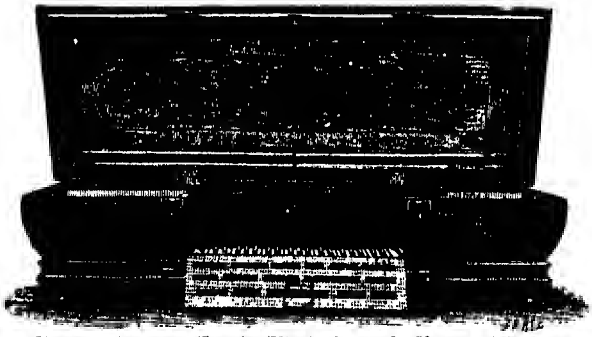

Fig. 9.—Spinetta Tavola (Virginal), 1568; Vict. and Albert Museum.

Mersenne (*op. cit.* liv. iii., p. 158) gives three sizes for spinets—one 2½ ft. wide, tuned to the octave of the "ton de chapelle" (in his day a half tone above the present English medium pitch), one of 3½ ft. tuned to the fourth below, and one of 5 ft. tuned to the octave below the first, the last being therefore tuned in unison to the chapel pitch. He says his own spinet was one of the smallest it was customary to make, but from the lettering of the keys in his drawing it would have been of the second size, or the spinet tuned to the fourth. The octave spinet, of trapeze form, was known in Italy as "ottavina" or "spinetta di serenata." It had a less compass of keys than the larger instrument, being apparently three and two-third octaves, E to C—which by the "short measure" would be four octaves, C to C. We learn from Praetorius that these little spinets were placed upon the larger ones in performance; their use was to heighten the brilliant effect. In the double rectangular clavisingel of the Netherlands, in which there was a movable octave instrument, we recognize a similar intention. There is a fine spinet of this

Fig. 10.—English Spinet (Spinetta Traversa), by Carolus Haward. About 1668.

kind at Nuremberg. Praetorius illustrates the Italian spinet by a form known as the "spinetta traversa," an approach towards the long clavicembalo or harpsichord, the tuning pins being immediately over the keyboard. This transposed spinet, more powerful than the old trapeze one, became fashionable in England after the Restoration, Haward, Keene, Slade, Player, Baudin, the Hitchcocks, Mahoon, Haxby, the Harrir family, and others having made such "spinets" during a period for which we have dates from 1664 to 1784. Pepys bought his "Espinette" from Charles Haward for £5, July 13, 1664.

The spinets of Keene and Player, made about 1700, have frequently two divided sharps at the bass end of the keyboard, as in the description by Mersenne, quoted above, of a spinet with short measure. Such divided sharps have been assumed to be quarter tones, but enharmonic intervals in the extreme bass can have no justification. From the tuning of Handel's Italian clavichord already mentioned, which has this peculiarity, and from Praetorius we find the further halves of the two divided sharps were the chromatic semitones, and the nearer halves the major thirds below, *i.e.* the dominant fourths to the next natural keys. Thomas Hitchcock (for whom there are dates 1664 and 1703 written on keys and jacks of spinets bearing Edward Blunt's name and having divided bass sharps) made a great advance in constructing spinets, giving them the wide compass of five octaves, from G to G, with very fine keyboards in which the sharps were inlaid with a slip of the ivory or ebony, as the case might be, of the naturals. Their instruments, always numbered, and not dated as has been sometimes supposed, became models for contemporary and subsequent English makers.

Harpsichord; Clavicymbal.

We have now to ask what was the difference between Scaliger's harpichordum and his clavicymbal. Galilei, the father of the astronomer of that name (*Dialogo della musica antica e moderna*, Florence, 1581), says that the harpichord was so named from having resembled an "arpa giacente," a prostrate or "couched" harp, proving that the clavicymbal was at first the trapeze-shaped spinet; and we should therefore differentiate harpichord and clavicymbal as, in form, suggested by or derived from the harp and psaltery, or from a "testa di porco" and an ordinary trapeze psaltery. We are inclined to prefer the latter. The Latin name "clavicymbalum," having early been replaced by spinet and virginal, was in Italy and France bestowed upon the long harpichord, and was continued as clavicembalo (gravecembalo, or familiarly cembalo only) and clavecin. Much later, after the restoration of the Stuarts, the first name was accepted and naturalized in England as harpsichord, which we will define as the long instrument with quills, shaped like a modern grand piano, and resembling a wing, from which it has gained the German appellation "Flügel." We can point out no long instrument of this kind so old as the Roman cembalo at South Kensington (fig. 11). It was made by Geronimo of Bologna in 1521, two years before the Paris Portalupis spinet. The outer case is of finely tooled leather. It has a spinet keyboard with a compass of nearly four octaves, E to D. The natural keys are of boxwood, gracefully arcaded in front. The keyboard of the Italian cembalo was afterwards carried out to the normal four octaves. There is an existing example, dated 1626, with the bass keys carried out without sharps in long measure (unfortunately altered by a restorer). It is surprising to see with what steady persistence the Italians adhered to their original model in making the instrument. As late as the epoch of Cristofori,[1] and in his 1722 cembalo at Florence,[2] we still find the independent outer case, the single keyboard, the two unisons, without power to reduce to one by using stops. The Italians have been as conservative with their forms of spinet, and are to this day with their organs. The startling "piano e forte" of 1598, brought to light from the records of the house of D'Este by Count Valdrighi of Modena,[3] after much consideration and a desire to find in it an anticipation of Cristofori's subsequent invention of the pianoforte, we are disposed to regard as an ordinary cembalo with power to shift, by a stop,

[1] In the harpsichord Cristofori made for Prince Ferdinand dei Medici in 1702, recently acquired by Mr Stearns, of Detroit, and presented by him to the University of Michigan, U.S.A., there are three keyboards, thus arranged: 1st, highest keyboard, octave string only; 2nd, middle, octave and first unison; 3rd, lowest, both unisons. A harpsichord similarly designed with three keyboards, inscribed "Vincentius Sodi Florentinus Fecit, Anno Domini 1779," was presented by Mrs J. Crosby Brown to the Metropolitan Museum, New York.

regal was derived from the rule (*regula*) or graduated scale of keys, and its use was to give the singers in religious processions the note or pitch. The only instrument of this kind known to exist in the United Kingdom is at Blair Atholl, and it bears the very late date of 1630. The Brussels regal [1] may be as modern. These are instances of how long a some-time admired musical instrument may remain in use after its first intention is forgotten. We attribute the adaptation of the narrow regal keyboard to what was still called the monochord, but was now a complex of monochords over one resonance board, to the latter half of the 14th century; it was accomplished by the substitution of tangents fixed in the further ends of the balanced keys for the movable bridges of the monochord or such stoppers as are shown in the Shrewsbury carving. Thus the monochordium or "payre of monochordis" became the clavichordium or "payre of clavichordis"—pair being applied, in the old sense of a "pair of steps," to a series of degrees. This use of the word to imply gradation was common in England to all keyed instruments; thus we read, in the Tudor period and later, of a pair of regals, organs, or virginals. Ed. van der Straten [2] reproduces a so-called clavichord of the 15th century from a MS. in the public library at Ghent. The treatise is anonymous, but other treatises in the same MS. bear dates 1503 and 1504. Van der Straeten is of opinion that the drawing may be assigned to the middle of the 15th century. The scribe calls the instrument a clavicimbalum, and this is undoubtedly correct; the 8 strings in the drawing are stretched from back to front over a long soundboard, the longest strings to the left; 8 keys, 4 long and 4 short with levers to which are attached the jacks, are seen in a horizontal line behind the keyboard, and behind them again are given the names of the notes a, b, c, d, e, f, g, h. In the Weimar *Wunderbuch* is a pen-and-ink sketch of the "clavicimbalum" [3] placed upon a table, in which we recognize the familiar outline of the harpsichord, but on a smaller scale. The keyboard shows white and black notes—the latter short keys, one between each group of two white keys, precisely as in the instrument reproduced by Van der Straeten—but no mechanism is visible under the strings.

The earliest known record of the clavichord occurs in some rules of the minnesingers,[4] dated 1404, preserved at Vienna. The monochord is named with it, showing a differentiation of these instruments, and of them from the clavicymbalum, the keyed cymbal, cembalo (Italian), or psaltery. From this we learn that a keyboard had been thus early adapted to that favourite medieval stringed instrument, the "cembalo" of Boccaccio, the "sautrie" of Chaucer. There were two forms of the psaltery: (1) the trapeze, one of the oldest representations of which is to be found in Orcagna's famous Trionfo della Morte in the Campo Santo at Pisa, and another by the same painter in the National Gallery, London; and (2) the contemporary "testa di porco," the pig's head, which was of triangular shape as the name suggests. The trapeze psaltery was strung horizontally, the "istromento di porco" either horizontally or vertically—the notes, as in the common dulcimer, being in groups of three or four unisons. In these differences of form and stringing we see the cause of the ultimate differentiation of the spinet and harpsichord. The compass of the psalteries was nearly that of Guido's scale; but according to Mersenne,[5] the lowest interval was a fourth, G to C, which is worthy of notice as anticipating the later "short measure" [6] of the spinet and organ.

The simplicity of the clavichord inclines us to place it, in order of time, before the clavicymbalum or clavicembalo; but we do not know how the sounds of the latter were at first excited. There is an indication as to its early form to be seen in the church of the Certosa near Pavia, which compares in probable date with the Shrewsbury example. We quote the reference to it from Dr Ambros.[7] He says a carving represents King David as holding an "istromento di porco" which has eight strings and as many keys lying parallel to them; inside the body of the instrument, which is open at the side nearest the right hand of King David, he touches the keys with the right hand and damps the strings with the left. The attribution of archaism applies with equal force to this carving as to the Shrewsbury one, for when the monastery of Certosa near Pavia was built by Ambrogio Fossana in 1472, chromatic keyboards, which imply a considerable advance, were already in use. There is an authentic representation of a chromatic keyboard, painted not later than 1426, in the St Cecilia panel (now at Berlin) of the famous Adoration of the Lamb by the Van Eycks. The instrument depicted is a positive organ, and it is interesting to notice in this realistic painting that the keys are evidently boxwood, as in the Italian spinets of later date, and that the angel plays a common chord—A with the right hand, F and C with the left. But diatonic organs with eight steps or keys in the octave, which included the B flat and the B natural, as in Guido's scale, were long preserved, for Praetorius speaks of them as still existing nearly two hundred years later. This diatonic keyboard, we learn from Sebastian Virdung (*Musica getutscht und auszgezogen*, Basel, 1511), was the keyboard of the early clavichord. We reproduce his diagram as the only authority we have for the disposition of the one short key.

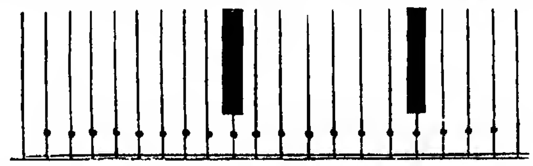

FIG. 2.—Diatonic Clavichord Keyboard (Guido's Scale) from Virdung. Before 1511.

The extent of this scale is exactly Guido's. Virdung's diagram of the chromatic is the same as our own familiar keyboard, and comprises three octaves and a note, from F below the bass stave to G above the treble. But Virdung tells us that even then clavichords were made longer than four octaves by repetition of the same order of keys. The introduction of the chromatic order he attributes to the study of Boetius, and the consequent endeavour to restore the three musical *genera* of the Greeks—the diatonic, chromatic and enharmonic. But the last-named had not been attained. Virdung gives woodcuts of the clavichordium, the virginal, the clavicymbalum and the clavicytherium. We reproduce three of them (figs. 3, 6 and 12), omitting the virginal as obviously incorrect. Writers on musical instruments have continually repeated these drawings without discerning that in the printing they are reversed, which puts the keyboards entirely wrong, and that in Luscinius's Latin translation of Virdung (*Musurgia, sive praxis musicae*, Strasburg, 1536), which has been hitherto chiefly followed, two of the engravings, the clavicimbalum and the clavicytherium, are transposed, another cause of error. Martin Agricola (*Musica instrumentalis*, Wittenberg, 1529) has copied Virdung's illustrations with some differences of perspective, and the addition, here and there, of errors of his own.

only; the lower keyboard to the second unison. Releasing the machine stop and quitting the pedal restores the first unison on both keyboards and the octave on the lower. The right-hand pedal was to raise a hinged portion of the top or cover and thus gain some power of "swell" or crescendo, an invention of Roger Plenius,[1] to whom also the harp stop may be rightly attributed. This ingenious harpsichord maker had been stimulated to gain these effects by the nascent pianoforte which, as we shall find, he was the first to make in England. The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (?Haward) as early as 1676, as we learn from Mace's *Musick's Monument*, p. 235. The French makers preferred a kind of knee-pedal arrangement, known as the "genouillère," and sometimes a more complete muting by one long strip of buff leather, the "sourdine." As an improvement upon Plenius's clumsy swell, Shudi in 1769 patented the Venetian swell, a framing of louvres, like a Venetian blind, which opened by the movement of the pedal, and becoming in England a favourite addition to harpsichords, was early transferred to the organ, in which it replaced the rude "nag's-head" swell. A French harpsichord maker, Marius, whose name is remembered from a futile attempt to design a pianoforte action, invented a folding harpsichord, the "clavecin brisé," by which the instrument could be disposed of in a smaller space. One, which is preserved at Berlin, probably formed part of the camp baggage of Frederick the Great.

Cristofori's Invention of the Pianoforte.

It was formerly a custom with kings, princes and nobles to keep large collections of musical instruments for actual playing purposes, in the domestic and festive music of their courts. There are records of their inventories, and it was to keep such a collection in playing order that Prince Ferdinand dei Medici engaged a Paduan harpsichord maker, Bartolommeo Cristofori, the man of genius who invented and produced the pianoforte.[2] We fortunately possess the record of this invention in a literary form from a well-known writer, the Marchese Scipione Maffei; his description appeared in the *Giornale dei letterati d'Italia*, a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it, with a technically imperfect translation, in his *History of the Pianoforte*. We learn from it that in 1709 Christofori had completed four "gravecembali col piano e forte"—keyed-psalteries with soft and loud—three of them being of the long or usual harpsichord form. A synonym in Italian for the original cembalo (or psaltery) is "salterio," and if it were struck with hammers it became a "salterio tedesco" (the German *hackbrett*, or chopping board), the latter being the common dulcimer. Now the first notion of a pianoforte is a dulcimer with keys, and we may perhaps not be wrong in supposing that there had been many attempts and failures to put a keyboard to a dulcimer or hammers to a harpsichord before Cristofori successfully solved the problem. The sketch of his action in Maffei's essay shows an incomplete stage in the invention, although the kernel of it—the principle of escapement or the controlled rebound of the hammer—is already there. He obtains it by a centred lever (*linguetta mobile*) or hopper, working, when the key is depressed by the touch, in a small projection from the centred hammer-butt. The return, governed by a spring, must have been uncertain and incapable of further regulating than could be obtained by modifying the strength of the spring. Moreover, the hammer had each time to be raised the entire distance of its fall. There are, however, two pianofortes by Cristofori, dated respectively 1720 and 1726, which show a much improved, we may even say a perfected, construction, for the whole of an essential piano movement is there. The earlier instrument (now in the Metropolitan Museum, New York) has undergone considerable restoration, the original hollow hammer-head having been replaced by a modern one, and the hammer-butt, instead of being centred by means of the holes provided by Cristofori himself for the purpose, having been lengthened by a leather hinge screwed to the block;[3] but the 1726 one, which is in the Kraus Museum at Florence, retains the original leather hammer-heads. Both instruments possess alike a contrivance for determining the radius of the hopper, and both have been unexpectedly found to have the "check" (Ital. *paramartello*), which regulates the fall of the hammer according to the strength of the blow which has impelled it to the strings. After this discovery of the actual instruments of Cristofori there can be no longer douht as to the attribution of the invention to him in its initiation and its practical completion with escapement and check. To Cristofori we are indebted, not only for the power of playing *piano* and *forte*, but for the infinite variations of tone, or *nuances*, which render the instrument so delightful.

But his problem was not solved by the devising of a working action; there was much more to be done to install the pianoforte as a new musical instrument. The resonance, that most subtle

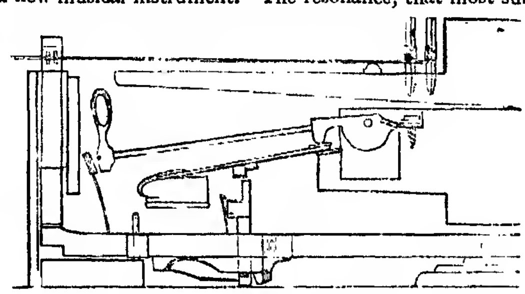

FIG. 13.—Cristofori's Escapement Action, 1720. Restored in 1875 by Cesare Ponsicchi.

and yet all-embracing factor, had been experimentally developed to a certain perfection by many generations of spinet and harpsichord makers, but the resistance structure had to be thought out again. Thicker stringing, rendered indispensable to withstand even Cristofori's light hammers, demanded in its turn a stronger framing than the harpsichord had needed. To make his structure firm he considerably increased the strength of the block which holds the tuning-pins, and as he could not do so without materially adding to its thickness, he adopted the bold expedient of inverting it; driving his wrest-pins, harp-fashion, through it, so that tuning was effected at their upper, while the wires were attached to their lower, ends. Then, to guarantee the security of the case, he ran an independent string-block round it of stouter wood than had been used in harpsichords, in which block the hitch-pins were driven to hold the farther ends of the strings, which were spaced at

FIG. 14.—Cristofori's Piano e Forte, 1726; Kraus Museum, Florence.

[1] Mace describes a primitive swell contrivance for an organ 95 years before Plenius took out his patent (1741).

[2] The invention of the piano by Cristofori, and him alone, is now past discussion. What is still required to satisfy curiosity would be the discovery of a Fort Bien or Frederici square piano, said to antedate by a year or two Zumpe's invention of the instrument in London. The name Fort Bien was derived, consciously or unconsciously, from the Saxon German peculiarity of interchanging B. and P. Among Mozart's effects at the time of his death was a *Forte-Biano mit Pedal* (see *Vierzehnter jährlicher Bericht des Mozarteum*, "Salzburg," Dec. 19, 1791). Also wanted is the "old movement" for the long or grand pianos, sometimes quoted in the Broadwood day-books of the last quarter of the 18th century with reference to the displacement by the Backers English action.

[3] Communicated by Baron Alexander Kraus (May 1908).

equal distances (unlike the harpsichord), the dampers lying between the pairs of unisons.

Cristofori died in 1731. He had pupils,[1] but did not found a school of Italian pianoforte-making, perhaps from the peculiar Italian conservatism in musical instruments we have already remarked upon. The essay of Scipione Maffei was translated into German, in 1725, by König, the court poet at Dresden, and friend of Gottfried Silbermann, the renowned organ builder and harpsichord and clavichord maker.[2] Incited by this publication, and perhaps by having seen in Dresden one of

Silbermann.

Cristofori's pianofortes, Silbermann appears to have taken up the new instrument, and in 1726 to have manufactured two, which J. S. Bach, according to his pupil Agricola, pronounced failures. The trebles were too weak; the touch was too heavy. There has long been another version to this story, viz. that Silbermann borrowed the idea of his action from a very simple model contrived by a young musician named Schroeter, who had left it at the electoral court in 1721, and, quitting Saxony to travel, had not afterwards claimed it. It may be so; but Schroeter's letter, printed in Mitzler's *Bibliothek*, dated 1738, is not supported by any other evidence than the recent discovery of an altered German harpsichord, the hammer action of which, in its simplicity, may have been taken from Schroeter's diagram, and would sufficiently account for the condemnation of Silbermann's earliest pianofortes if he had made use of it. In either case it is easy to distinguish between the lines of Schroeter's interesting communications (to Mitzler, and later to Marpurg) the bitter disappointment he felt in being left out of the practical development of so important an instrument.

But, whatever Silbermann's first experiments were based upon, it was ascertained, by the investigations of A. J. Hipkins, that he, when successful, adopted Cristofori's pianoforte without further alteration than the compass and colour of the keys and the style of joinery of the case. In the Silbermann grand pianofortes, in the three palaces at Potsdam, known to have been Frederick the Great's, and to have been acquired by that monarch prior to J. S. Bach's visit to him in 1747, we find the Cristofori framing, stringing, inverted wrest-plank and action complete. Fig. 15 represents the instrument on which J. S. Bach played in the Town Palace, Potsdam.

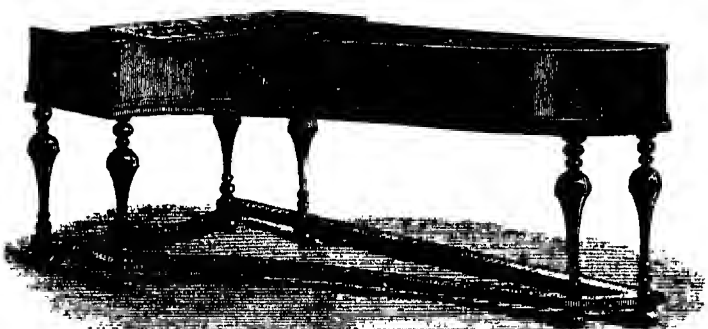

Fig. 15.—Silbermann Forte Piano; Stadtschloss, Potsdam, 1746.

It has been repeatedly stated in Germany that Frederici, of Gera in Saxony, an organ builder and musical instrument

Frederici.

maker, invented the square or table-shaped piano, the "fort bien," as he is said to have called it, about 1758–1760. No square piano by this maker is forthcoming, though an "upright grand" piano, made by Domenico del Mela in 1739, with an action adapted from Cristofori's, has been discovered by Signor Ponsicchi of Florence. Victor Mahillon of Brussels, however, acquired a Frederici "upright grand" piano, dated 1745 (fig. 16). In Frederici's upright grand action we have not to do with the ideas of either Cristofori or Schroeter; the movement is practically identical with the hammer action of a German clock, and has its counterpart in a piano at Nuremberg; a fact which needs further elucidation. We note here the earliest example of the leather hinge, afterwards so common in piano actions and only now going out of use. Where are we to look for Schroeter's copyist if not found in Silbermann, Frederici, or, as we shall presently see, perhaps J. G. Wagner? It might be in the harpsichord we have mentioned, which, made in 1712 by one Brock for the elector of Hanover (afterwards George I. of England), was by him presented to the Protestant pastor of Schulenberg, near Hanover, and has since been rudely altered into a pianoforte (fig. 17). There is an altered harpsichord in the museum at Basel which appears to have been no more successful. But an attempted combination of harpsichord and pianoforte appears as a very early intention. The English poet Mason, the friend of Gray, bought such an instrument at Hamburg in 1755, with "the cleverest mechanism imaginable."

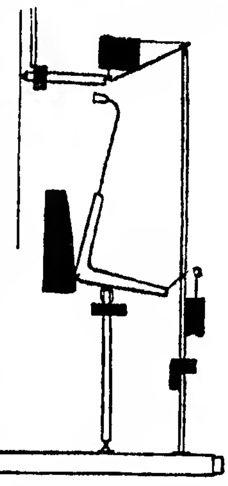

Fig. 16.—Frederici's Upright Grand Piano Action, 1745. In the museum of the Brussels Conservatoire.

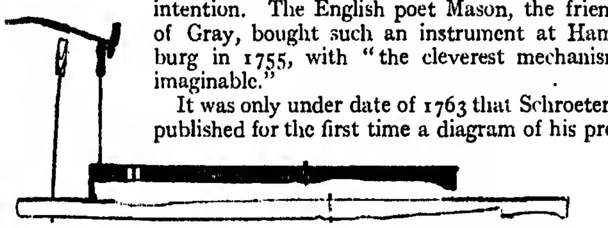

Fig. 17.—Hammer and Lifter of altered Harpsichord by Brock. Instrument in the collection of Mr Kendrick Pyne, Manchester.

It was only under date of 1763 that Schroeter[3] published for the first time a diagram of his proposed invention, designed more than forty years before. It appeared in Marpurg's *Kritische Briefe* (Berlin, 1764). Now, immediately after,

Schroeter; Zumpe.

Johann Zumpe, a German in London, who had been one of Shudi's workmen, invented or introduced (for there is some tradition that Mason had to do with the invention of it[4]) a square piano, which was to become the most popular domestic instrument. It would seem that Zumpe was in fact not the inventor of the square piano, which appears to have been well known in Germany before his date, a discovery made by Mr George Rose. In Paul de Wit's Musical Instrument Museum—formerly in Leipzig, now transferred to Cologne—there is a small square piano, 27 in. long, 10 in. wide, and 4½ in. high, having a contracted keyboard of 3 octaves and 2 notes. The action of this small instrument is practically identical in every detail with that of the square pianofortes made much later by Zumpe (Paul de Wit, *Katalog. des musikhistorischen Museums*, Leipzig, 1903, No. 55, illustration, p. 38). Inside is inscribed: "Friedrich Hildebrandt, Instrumentenmacher in Leipzig, Quergasse," with four figures

[1] See Cesare Ponsicchi, *Il Pianoforte, sua origine e sviluppo* (Florence, 1876), p. 37.

[2] This translation, published at Hamburg and reproduced *in extenso*, may be read in Dr Oscar Paul's *Geschichte des Claviers* (Leipzig, 1868).

[3] For arguments in favour of Schroeter's claim to the invention of the pianoforte see Dr Oscar Paul, *op. cit.* pp. 85–104, who was answered by A. J. Hipkins in Grove's *Dict. of Music and Musicians*.

[4] Mason really invented the "celestina" (known as Adam Walker's patent, No. 1020), as we know from the correspondence of Mary Granville. Under date of the 11th of January 1775 she describes this invention as a short harpsichord 2 ft. long, but played with the right hand only. The left hand controlled a kind of violin-bow, which produced a charming *sostinente*, in character of tone between the violin tone and that of musical glasses.

only; the lower keyboard to the second unison. Releasing the machine stop and quitting the pedal restores the first unison on both keyboards and the octave on the lower. The right-hand pedal was to raise a hinged portion of the top or cover and thus gain some power of "swell" or crescendo, an invention of Roger Plenius,[1] to whom also the harp stop may be rightly attributed. This ingenious harpsichord maker had been stimulated to gain these effects by the nascent pianoforte which, as we shall find, he was the first to make in England. The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (?Haward) as early as 1676, as we learn from Mace's *Musick's Monument*, p. 235. The French makers preferred a kind of knee-pedal arrangement, known as the "genouillère," and sometimes a more complete muting by one long strip of buff leather, the "sourdine." As an improvement upon Plenius's clumsy swell, Shudi in 1769 patented the Venetian swell, a framing of louvres, like a Venetian blind, which opened by the movement of the pedal, and becoming in England a favourite addition to harpsichords, was early transferred to the organ, in which it replaced the rude "nag's-head" swell. A French harpsichord maker, Marius, whose name is remembered from a futile attempt to design a pianoforte action, invented a folding harpsichord, the "clavecin brisé," by which the instrument could be disposed of in a smaller space. One, which is preserved at Berlin, probably formed part of the camp baggage of Frederick the Great.

Cristofori's Invention of the Pianoforte.

It was formerly a custom with kings, princes and nobles to keep large collections of musical instruments for actual playing purposes, in the domestic and festive music of their courts. There are records of their inventories, and it was to keep such a collection in playing order that Prince Ferdinand dei Medici engaged a Paduan harpsichord maker, Bartolommeo Cristofori, the man of genius who invented and produced the pianoforte.[2] We fortunately possess the record of this invention in a literary form from a well-known writer, the Marchese Scipione Maffei; his description appeared in the *Giornale dei letterati d'Italia*, a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it, with a technically imperfect translation, in his *History of the Pianoforte*. We learn from it that in 1709 Christofori had completed four "gravecembali col piano e forte"—keyed-psalteries with soft and loud—three of them being of the long or usual harpsichord form. A synonym in Italian for the original cembalo (or psaltery) is "salterio," and if it were struck with hammers it became a "salterio tedesco" (the German *hackbrett*, or chopping board), the latter being the common dulcimer. Now the first notion of a pianoforte is a dulcimer with keys, and we may perhaps not be wrong in supposing that there had been many attempts and failures to put a keyboard to a dulcimer or hammers to a harpsichord before Cristofori successfully solved the problem. The sketch of his action in Maffei's essay shows an incomplete stage in the invention, although the kernel of it—the principle of escapement or the controlled rebound of the hammer—is already there. He obtains it by a centred lever (*linguetta mobile*) or hopper, working, when the key is depressed by the touch, in a small projection from the centred hammer-butt. The return, governed by a spring, must have been uncertain and incapable of further regulating than could be obtained by modifying the strength of the spring. Moreover, the hammer had each time to be raised the entire distance of its fall. There are, however, two pianofortes by Cristofori, dated respectively 1720 and 1726, which show a much improved, we may even say a perfected, construction, for the whole of an essential piano movement is there. The earlier instrument (now in the Metropolitan Museum, New York) has undergone considerable restoration, the original hollow hammer-head having been replaced by a modern one, and the hammer-butt, instead of being centred by means of the holes provided by Cristofori himself for the purpose, having been lengthened by a leather hinge screwed to the block;[3] but the 1726 one, which is in the Kraus Museum at Florence, retains the original leather hammer-heads. Both instruments possess alike a contrivance for determining the radius of the hopper, and both have been unexpectedly found to have the "check" (Ital. *paramartello*), which regulates the fall of the hammer according to the strength of the blow which has impelled it to the strings. After this discovery of the actual instruments of Cristofori there can be no longer doubt as to the attribution of the invention to him in its initiation and its practical completion with escapement and check. To Cristofori we are indebted, not only for the power of playing *piano* and *forte*, but for the infinite variations of tone, or *nuances*, which render the instrument so delightful.

But his problem was not solved by the devising of a working action; there was much more to be done to install the pianoforte as a new musical instrument. The resonance, that most subtle

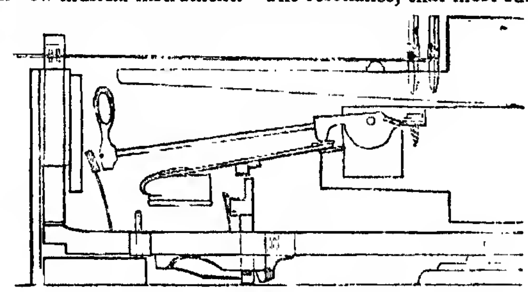

Fig. 13.—Cristofori's Escapement Action, 1720. Restored in 1875 by Cesare Ponsicchi.

and yet all-embracing factor, had been experimentally developed to a certain perfection by many generations of spinet and harpsichord makers, but the resistance structure had to be thought out again. Thicker stringing, rendered indispensable to withstand even Cristofori's light hammers, demanded in its turn a stronger framing than the harpsichord had needed. To make his structure firm he considerably increased the strength of the block which holds the tuning-pins, and as he could not do so without materially adding to its thickness, he adopted the bold expedient of inverting it; driving his wrest-pins, harp-fashion, through it, so that tuning was effected at their upper, while the wires were attached to their lower, ends. Then, to guarantee the security of the case, he ran an independent string-block round it of stouter wood than had been used in harpsichords, in which block the hitch-pins were driven to hold the farther ends of the strings, which were spaced at

[1] Mace describes a primitive swell contrivance for an organ 95 years before Plenius took out his patent (1741).

[2] The invention of the piano by Cristofori, and him alone, is now past discussion. What is still required to satisfy curiosity would be the discovery of a Fort Bien or Frederici square piano, said to antedate by a year or two Zumpe's invention of the instrument in London. The name Fort Bien was derived, consciously or unconsciously, from the Saxon German peculiarity of interchanging B. and P. Among Mozart's effects at the time of his death was a *Forte-Biano mit Pedal* (see *Vierzehnter jährlicher Bericht des Mozarteum*, "Salzburg," Dec. 19, 1791). Also wanted is the "old movement" for the long or grand pianos, sometimes quoted in the Broadwood day-books of the last quarter of the 18th century with reference to the displacement by the Backers English action.

[3] Communicated by Baron Alexander Kraus (May 1908).

harpsichord, in 1745. When Mason imported a pianoforte in 1755, Fulke Greville's could have been no longer unique. The Italian origin of Father Wood's piano points to a copy of Cristofori, but the description of its capabilities in no way confirms this supposition, unless we adopt the very possible theory that the instrument had arrived out of order and there was no one in London who could put it right, or would perhaps divine that it was wrong. Burney further tells us that the arrival in London of J. C. Bach in 1759 was the motive for several of the second-rate harpsichord makers trying to make pianofortes, but with no particular success. Of these Americus Backers (d. 1776), said to be a Dutchman, appears to have gained the first place. He was afterwards the inventor of the so-called English action, and as this action is based upon Cristofori's we may suppose he at first followed Silbermann in

Backers.

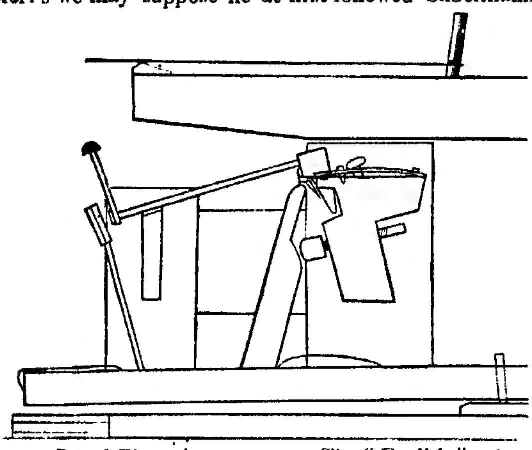

Fig. 23.—Grand Piano Action, 1776. The "English" action of Americus Backers.

copying the original inventor. There is an old play-bill of Covent Garden in Messrs Broadwood's possession dated the 16th of May 1767, which has the following announcement:—

"End of Act I. Miss Brickler will sing a favourite song from *Judith*, accompanied by Mr Dibdin on a new instrument call'd Piano Forte."

The mind at once reverts to Backers as the probable maker of this novelty. Backers's "Original Forte Piano" was played at the Thatched House in St James's Street, London, in 1773. Ponsicchi has found a Backers grand piano at Pistoria, dated that year. It was Backers who produced the action continued in the direct principle by the firm of Broadwood, or with the reversed lever and hammer-butt introduced by the firm of Collard in 1835.

The escapement lever is suggested by Cristofori's first action, to which Backers has added a contrivance for regulating it by means of a button and screw. The check is from Cristofori's second action. No more durable action has been constructed, and it has always been found equal, whether made in England or abroad, to the demands of the

most advanced virtuosi. John Broadwood and Robert Stodart were friends, Stodart having been Broadwood's pupil; and they were the assistants of Backers in the installation of his invention. On his death-bed he commended it to Broadwood's care, but Stodart appears to have been the first to advance it—Broadwood being probably held back by his partnership with his brother-in-law, the son of Shudi, in the harpsichord business. (The elder Shudi had died in 1773.) Stodart soon made a considerable reputation with his "grand" pianofortes, a designation he was the first to give them. In Stodart's grand piano we first find an adaptation from the lyrichord of Plenius, of steel arches between the

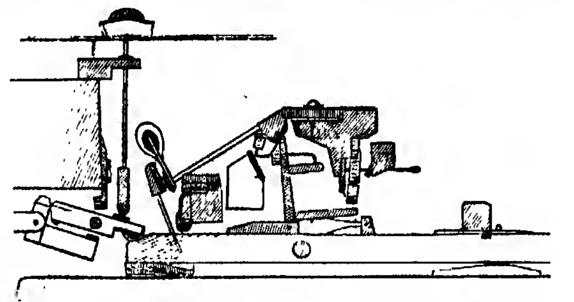

Fig. 25.—Collard's Grand Piano Action, 1884. English action, with reversed hopper and contrivance for repetition added.

wrest-plank and belly-rail, bridging the gap up which the hammers rise, in itself an important cause of weakness. These are not found in any contemporary German instruments, but may have been part of Backers's.

Imitation of the harpsichord by "octaving" was at this time an object with piano makers. Zumpe's small square piano had met with great success; he was soon enabled to retire, and his imitators, who were legion, continued his model with its hand stops for the dampers and sourdine, with little change but that which straightened the keys from the divergences inherited from the clavichord. John Broadwood took this domestic instrument first in hand to improve it, and in the year 1780 succeeded in entirely reconstructing it. He transferred the wrest-plank and pins from the right-hand side, as in the clavichord, to the back of the case, an improvement universally adopted after his patent, No. 1379 of 1783, expired. In this patent we first find the damper and piano pedals, since universally accepted, but at first in the grand pianofortes only. Zumpe's action remaining with an altered damper, another inventor, John Geib, patented (No. 1571 of 1786) the hopper with two separate escapements, one of which soon became adopted in the grasshopper of the square piano, it is believed by Geib himself; and Petzold, a Paris maker, appears to have taken later to the escapement effected upon the key. We may mention here that the square piano was developed and continued in England until about the year 1860, when it went out of fashion.

To return to John Broadwood—having launched his reconstructed square piano, he next turned his attention to the grand piano to continue the improvement of it from the point where Backers had left it. The grand piano was in framing and resonance entirely on the harpsichord principle, the sound-board bridge being still continued in one undivided length. The strings, which were of brass wire in the bass, descended in notes of three unisons to the lowest note of the scale. Tension was left to chance, and a reasonable striking line or place for the hammers was not thought of. Theory requires that the notes of octaves should be multiples in the ratio of 1 to 2, by which, taking the treble clef C at one foot, the lowest F of the five-octave scale would require a vibrating length between the bridges of 12 ft. As only half this length could be conveniently afforded, we see at once a reason for the above-mentioned deficiencies. Only the three octaves of the treble, which had lengths practically ideal, could be tolerably adjusted. Then the striking-line, which should be at an eighth or not less than a nine or tenth of the vibrating length, and had never been cared for in the harpsichord, was in the lowest two octaves out of all proportion, with corresponding disadvantage to the tone. John Broadwood did not venture alone upon the path

towards rectifying these faults. He called in the aid of professed men of science—Tiberius Cavallo, who in 1788 published his calculations of the tension, and Dr Gray, of the British Museum. The problem was solved by dividing the sound-board bridge, the lower half of which was advanced to carry the bass strings, which were still of brass. The first attempts to equalize the tension and improve the striking-place were here set forth, to the great advantage of the instrument, which in its wooden construction might now be considered complete. The greatest pianists of that epoch, except Mozart and Beethoven, were assembled in London—Clementi, who first gave the pianoforte its own character, raising it from being a mere variety of the harpsichord, his pupils Cramer and for a time Hummel, later on John Field, and also the brilliant virtuosi Dussek and Steibelt. To please Dussek, Broadwood in 1791 carried his five-octave, F to F, keyboard, by adding keys upwards, to five and a half octaves, F to C. In 1794 the additional bass half octave to C, which Shudi had first introduced in his double harpsichords, was given to the piano. Steibelt, while in England, instituted the familiar signs for the employment of the pedals, which owes its charm to excitement of the imagination instigated by power over an acoustical phenomenon, the sympathetic vibration of the strings. In 1799 Clementi founded a pianoforte manufactory, to be subsequently developed and carried on by Messrs Collard.

The first square piano made in France is said to have been constructed in 1776 by Sebastian Erard, a young Alsatian.

Erard.

In 1786 he came to England and founded the London manufactory of harps and pianofortes bearing his name. That eminent mechanician and inventor is said to have at first adopted for his pianos the English models.

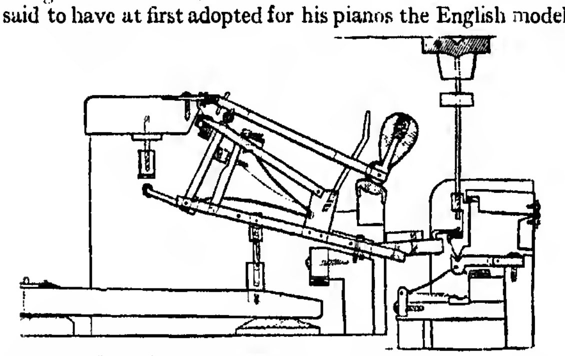

Fig. 26.—Erard's Double Escapement Action, 1884. The double escapement or repetition is effected by a spring in the balance pressing the hinged lever upwards, to allow the hopper which delivers the blow to return to its position under the nose of the hammer, before the key has risen again.

However, in 1794 and 1801, as is shown by his patents, he was certainly engaged upon the elementary action described as appertaining to Gosselin's piano, of probably German origin. In his long-continued labour of inventing and constructing a double escapement action, Erard appears to have sought to combine the English power of gradation of tone with the German lightness of touch. He took out his first patent for a "repetition" action in 1808, claiming for it "the power of giving repeated strokes without missing or failure, by very small angular motions of the key itself." He did not, however, succeed in producing his famous repetition or double escapement action until 1821; it was then patented by his nephew Pierre Erard, who, when the patent expired in England in 1835, proved a loss from the difficulties of carrying out the invention, which induced the House of Lords to grant an extension of the patent.

Erard invented in 1808 an upward bearing to the wrest-plank bridge, by means of agraffes or studs of metal through holes in which the strings are made to pass, bearing against the upper side. The wooden bridge with down-bearing strings is clearly not in relation with upward-striking hammers, the tendency of which must be to raise the strings from the bridge, to the detriment of the tone. A long brass bridge on this principle was introduced by William Stodart in 1822. A pressure-bar bearing of later introduction is claimed for the French maker, Bord. The first to see the importance of iron sharing with wood (ultimately almost supplanting it) in pianoforte framing was a native of England and a civil engineer by profession, John Isaac Hawkins, known as the inventor of the ever-pointed pencil. He was living at Philadelphia, U.S.A., when he invented and first produced the familiar

Hawkins.

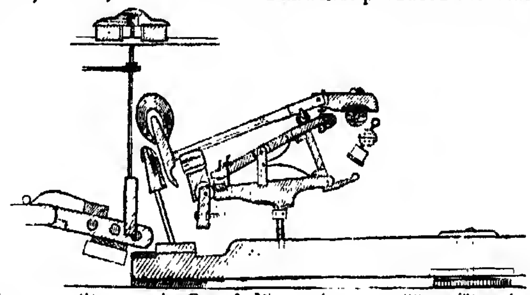

Fig. 27.—Steinway's Grand Piano Action, 1884. The double escapement as in Erard's, but with shortened balance and usual check.

cottage pianoforte—"portable grand" as he then called it. He patented it in America, his father, Isaac Hawkins, taking out the patent for him in England in the same year, 1800. It will be observed that the illustration here given (fig. 28) represents a wreck; but a draughtsman's restoration might be open to question.

There had been upright grand pianos as well as upright harpsichords, the horizontal instrument being turned up upon its wider end and a keyboard and action adapted to it. William Southwell, an Irish piano-maker, had in 1798 tried a similar experiment with a square piano, to be repeated in later years by W. F. Collard of London; but Hawkins was the first to make a piano, or pianino, with the strings descending to the floor, the keyboard being raised, and this, although at the moment the chief, was not his only merit. He anticipated nearly every

Fig. 28.—Hawkins's Portable Grand Piano, 1800. An upright instrument, the original of the modern cottage piano or pianino. In Messrs Broadwood's museum and unrestored.

discovery that has since been introduced as novel. His instrument (fig. 28) is in a complete iron frame, independent of the case; and in this frame, strengthened by a system of iron resistance rods combined with an iron upper bridge, his sound-board is entirely suspended. An apparatus for tuning by mechanical screws regulates the tension of the strings, which are of equal length throughout. The action, in metal supports, anticipates Wornum's in the checking, and still later ideas in a contrivance for repetition. This remarkable bundle of inventions was brought to London and exhibited by Hawkins himself;

harpsichord, in 1745. When Mason imported a pianoforte in 1755, Fulke Greville's could have been no longer unique. The Italian origin of Father Wood's piano points to a copy of Cristofori, but the description of its capabilities in no way confirms this supposition, unless we adopt the very possible theory that the instrument had arrived out of order and there was no one in London who could put it right, or would perhaps divine that it was wrong. Then the striking-line, which should be at an eighth or not less than a nine or tenth of the vibrating length, and had never been cared for in the harpsichord, was in the lowest two octaves out of all proportion, with corresponding disadvantage to the tone. John Broadwood did not venture alone upon the path

Mr Henry Fowler Broadwood, son of James, and grandson of John Broadwood, and also great-grandson of Shudi (Tschudi), invented a grand pianoforte to depend practically upon iron, in which, to avoid the conspicuous inequalities caused by the breaking of the scale with resistance bars, there should be no bar parallel to the strings except a bass bar, while another flanged resistance bar, as an entirely novel feature, crossed over the strings from the bass corner of the wrest-plank to a point upon the string-plate where the greatest accumulation of tension strain was found. Broadwood did not continue, without some compromise, this extreme renunciation of ordinary resistance means. After the Great Exhibition of 1851 he employed an ordinary straight bar in the middle of his concert grand scale, his smaller grands having frequently two such as well as the long bass bar. After 1862 he covered his wrest-plank with a thick plate of iron into which the tuning pins screw as well as into the wood beneath, thus avoiding the crushing of the wood by the constant pressure of the pin across the pull of the string, an ultimate source of danger to durability.

The introduction of iron into pianoforte structure was differently and independently effected in America, the fundamental idea there being to use a single casting for the metal plate and bars, instead of forging or casting them in separate pieces. Alphaeus Babcock was the pioneer to this kind of metal construction. He also was bitten with the compensation notion, and had cast an iron ring for a square piano in 1825, which, although not a success, gave the clue to a single casting resistance framing, successfully accomplished by Conrad Meyer, in Philadelphia, in 1833, in a square piano which still exists, and was shown in the Paris Exhibition of 1878. Meyer's idea was improved upon by Jonas Chickering (1797–1853) of Boston, who applied it to the grand piano as well as to the square, and brought the principle up to a high degree of perfection—establishing by it the independent construction of the American pianoforte.

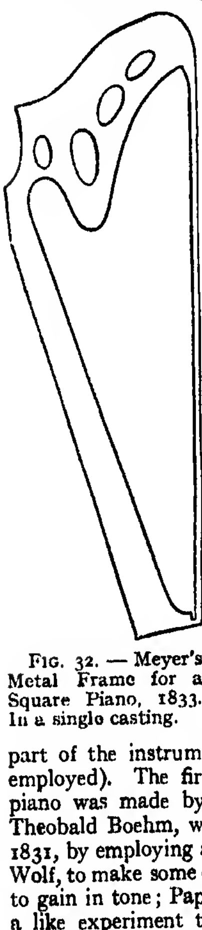

Fig. 32. — Meyer's Metal Frame for a Square Piano, 1833. In a single casting.

Over-stringing.

We have now to do with over- or cross-stringing, by which the bass division of the strings is made to cross over the tenor part of the scale in a single, double or treble disposition at diverging angles—the object being in the first instance to get longer bass strings than are attainable in a parallel scale, and in the next to open out the scale and extend the area of bridge pressure on the sound-board. In the 18th century clavichords were sometimes overstrung in the lowest octave to get a clearer tone in that very indistinct part of the instrument (strings tuned an octave higher being employed). The first suggestion for the overstringing in the piano was made by the celebrated flute-player and inventor Theobald Boehm, who carried it beyond theory in London, in 1831, by employing a small firm located in Cheapside, Gerock & Wolf, to make some overstrung pianos for him. Boehm expected to gain in tone; Pape, an ingenious mechanician in Paris, tried a like experiment to gain economy in dimensions, his notion being to supply the best piano possible with the least outlay of means. Tomkinson in London continued Pape's model, but neither Boehm's nor Pape's took permanent root. The Great Exhibition of 1851 contained a grand piano, made by Lichtenthal of St Petersburg, overstrung in order to gain symmetry by two angle sides to the case. It was regarded as a curiosity only. Later, in 1855, Henry Engelhard Steinway (originally Steinweg; 1797–1871), who had emigrated from Brunswick to New York in 1849, and had established the firm of Steinway & Sons in 1853 in that city, effected the combination of an overstrung scale with the American iron frame, which, exhibited in grand and square instruments shown in London in the International Exhibition of 1862, excited the attention of European pianoforte makers, leading ultimately to important results. The Chickering firm claim to have anticipated the Steinways in this invention. They assert that Jonas Chickering had begun a square piano on this combined system in 1853, but, he died before it was completed, and it was brought out later. It is often difficult to adjudicate upon the claims of inventors, so rarely is an invention the product of one man's mind alone. However, the principle was taken up and generally adopted in America and Germany, and found followers elsewhere, not only in grand but in upright pianos, to the manufacture of which it gave, and particularly in Germany, a powerful impetus.

Steinway.

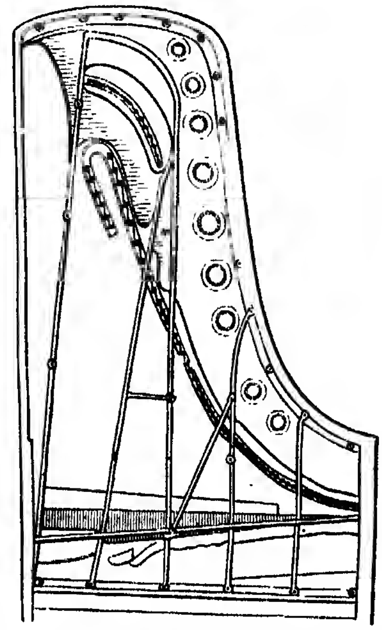

Fig. 33.—Steinway's Grand Piano, 1884. Metal framing in a single casting and overstrung.

Recent Structural Changes.

Since 1885 the American system of a metal plate in one casting, and cross- or over-stringing by which the spun bass strings cross the longer steel diagonally, has become general in Europe with the exception of France, where musical taste has remained constant to the older wooden structure and parallel stringing throughout. The greater tenacity of the modern cast-steel wire favours a very much higher tension, and consequent easier production of the higher partials of the notes, permitting a *sostenuto* unknown to Beethoven, Schumann or Chopin. While in 1862 the highest tension of a concert grand piano worked out at sixteen tons, since 1885 thirty tons has been recorded. Generally speaking, the rise in tension may be expressed musically by the interval of a minor third, to the great advantage of the standing in tune. First shown by Henry Steinway in the London Exhibition of 1862, this altered construction attracted extraordinary attention at Paris in 1867, and determined the German direction of manufacture and a few years later the English. What is now particularly noticeable wherever pianos are made is the higher average of excellence attained in making, as well as in piano-playing. Naturally the artistic quality, the personal note, characterizes all first-class instruments, and permits that liberty of choice which appertains to a true conception of art.

Much attention has been given of late years to the touch of pianos, to make it less tiring for the modern performer, especially since, in 1885–1886, Anton Rubinstein went through the herculean feat of seven consecutive historical recitals, repeated in the capital cities and principal musical centres of Europe. For even this stupendous player a light touch was indispensable. In

the competition for power piano makers had been gradually increasing the weight of touch to be overcome by the finger, until, to obtain the faintest pianissimo from middle C, at the front edge of the key, from three to four ounces was a not uncommon weight. The Broadwood grand piano which Chopin used for his recitals in London and Manchester in 1848, an instrument that has never been repaired or altered, shows the resistance he required: the middle C sounds at two ounces and a half, and to that weight piano-makers have returned, regarding two ounces and three-quarters as a possible maximum. Owing to the greater substance of the hammers in the bass, the touch will

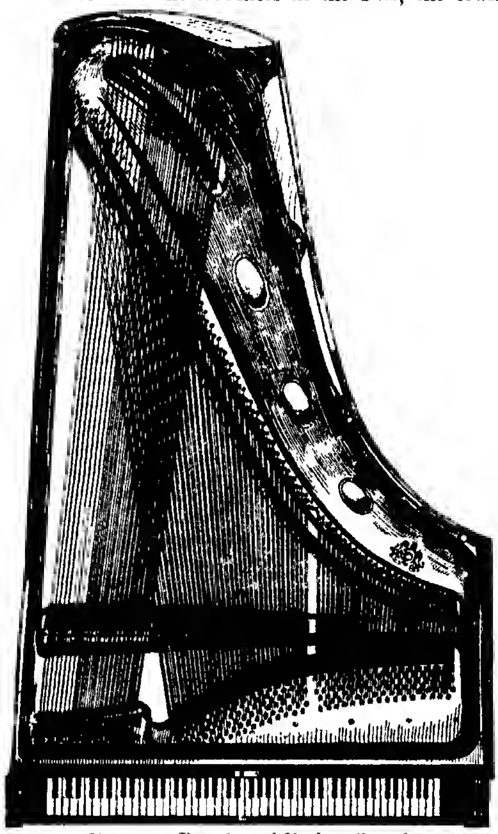

FIG. 34.—Broadwood Barless Grand.

always be heavier in that department, and lighter in the treble from the lesser weight. In balancing the keys, allowance has to be made for the shorter leverage of the black keys. When the player touches the keys farther back the leverage is proportionately shortened and the weight increased, and there is also an ascending scale in the weight of the player's blow or pressure from pianissimo to fortissimo. The sum of the aggregate force expended by a pianist in a recital of an hour and a half's duration, if calculated, would be astonishing.

The most important structural change in pianos in recent years has been the rejection of support given by metal bars or struts between the metal plate to which the strings are hitched and the wrest-plank wherein the tuning-pins are inserted. These bars formed part of William Allen's invention, brought forward by Stodart in 1820, and were first employed for rigidity in place of compensation by the Paris Erards two years later, Broadwood in London introducing about that time the fixed metal plate. The patent No. 1231, for the barless or open-scale piano, taken out in London in 1888 by H. J. Tschudi Broadwood, is remarkable for simplification of design as well as other qualities. Ten years elapsed after the taking out of the patent before the first *barless grand* was heard in public (January 1898 at St James's Hall). The metal frame, bolted in the usual manner to the bottom framing, is of fine cast steel entirely free from any transverse bars or struts, being instead turned up round the edges to form a continuous flange, which enables the frame to bear the increased modern tension while providing additional elasticity and equality of vibration power throughout the scaling. The absence of barring and bracing tends to subdue the metallic quality of tone so often observable in pianofortes constructed with heavy iron frames, and the barless steel frame being so much more elastic than the latter, no loss in resonance is perceptible. The tone of the barless grand is of singular beauty and sonority and is even throughout the compass.

The Increase of Resonance.

The problem of resonance—with stringed keyboard instruments, the reinforcement or amplification of sound—has, from the days of the lute- and spinet-makers, been empirical. With lute, guitar, and viol or violin the sound-box comes in, combining in the instrument the distinct properties of string and enclosed air or wind. With the spinet, harpsichord and piano we have to do chiefly with the plate of elastic wood, to amplify the initial sound of the strings; and the old plan of a thin plate of spruce, put in slightly convex and with an under-barring of wood for tension, has absorbed the attention of piano-makers. The violin belly, with its bass bar and sound post, has relation to it; but the recent invention of the Stroh violin has shown that the initial string vibrations may be passed through a bridge, be concentrated, and adequately transferred to an aluminium disk not much larger than half a crown. The piano, with its numerous strings, cannot be so reduced, but the reinforcement problem is open to another solution, tentative it is true, but a possible rival. The "Gladiator" soundboard is the invention of Albert Schulz, late director of the piano manufactory of Ritmüller und Söhne of Göttingen. Dr Moser's name has been associated with the inventor's in the English patent. In the "Gladiator" two slabs of wood, with grain of opposed direction to give the necessary tension, are glued together, and the whole system of belly bars is done away with. There is a thinning round the edge, to facilitate promptness of speech. As we are still feeling our way towards an accurate and comprehensive statement of resonance, this invention is one claiming scientific interest, as well as being of possible practical importance.

Repetition.

To return to the touch. The desirability of what is called repetition—that the jack or sticker, which from the depression of the key delivers the blow that raises the hammer to the strings, should never be far away from the notch or nose which receives the impulse—is as much an object of consideration with piano-makers now as it has been since Sebastian Erard began those experiments in 1808 which ended

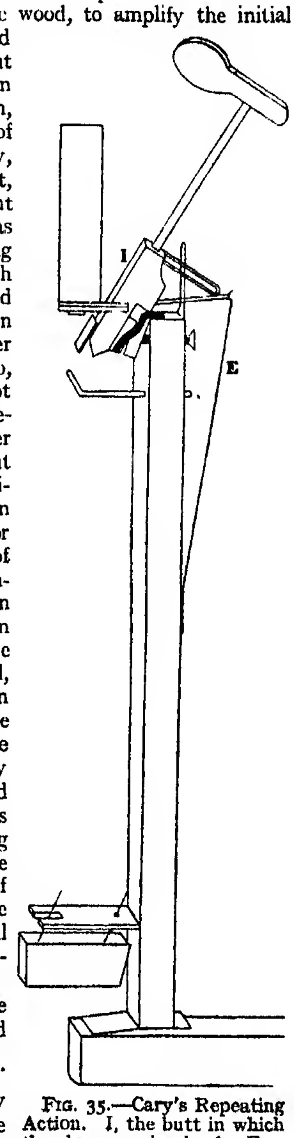

FIG. 35.—Cary's Repeating Action. I, the butt in which the hammer is glued. E, a spring attached to the butt by a link of silk cord passed through a wire guide. The object is that though the key may be still pressed down, the hammer returns but a short distance to ensure a quick response to the blow if repeated.

in his famous "double escapement" action. The principle of this grand action, like that of Wornum patented for upright pianos in 1826, has become general. But Joseph Henry Cary in 1853 (patent No. 2283) invented a simple contrivance for repetition in all pianos, neglected at the time, and subsequently repatented and disputed over by others, which has only been preserved in the records of the patent office, while the inventor has left no other mark. But the utility of the invention has come to light. It is increasingly used in the actions of upright pianos, and, in combination with the old English grand action, is successfully competing with the Erard action proper and the simplified Herz-Erard, of late years so very generally employed.

Technique.

There has been a great change in the freer technique of piano-playing, partly favoured by the development of piano-making, but reacting and obliging the piano-makers to keep their attention incessantly alive to the aim and requirements of the players. It is true that the genius of Beethoven dominates a technique that has become obsolete, and so completely that the adequate performance of his piano works still gives to the sense as well as the intellect the highest pleasure; but his annotations to Cramer's *Studies*, as preserved by Schindler, betray the close touch of the clavichord-player and the student of C. P. E Bach's *Essay on Clavichord-Playing*, as well as the weakness as a musical instrument of the early piano. The inventor of a technique so original, and at the time (*c.* 1830) so extraordinary, as Chopin's, sat at the piano with his elbows immovable, using, for flexibility, neither wrist nor arm. With Chopin, to play loudly was anathema. The modern free style of playing comes from Czerny—whom Beethoven despised as having no legato (*Bindung*)—through Liszt to the Rubinsteins and to the splendidly-equipped performers of our time, to whom the pedal has become indispensable for cantabile and effect.

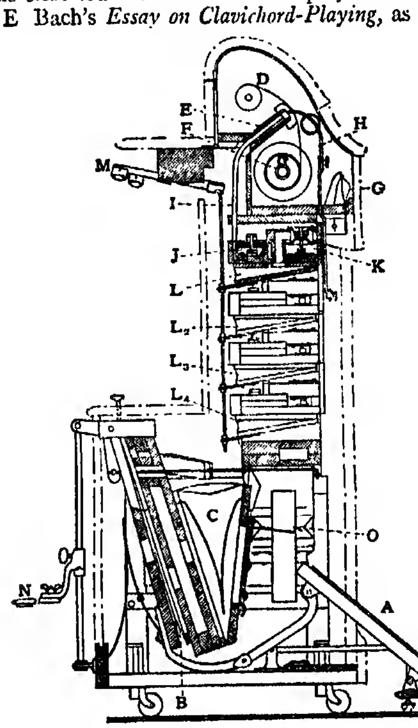

FIG. 36.—Modern Pianola.

A, Blowing pedals operated by feet of player connected by metal crank to feeder B, which exhausts air from bellows C, which in turn exhausts air from all working valves and bellows in Pianola.

D, is perforated roll passing over tracker bar E winding on to spool F operated by a pneumatic motor and controlled by lever G, which is connected to metrostyle pointer H. This is used in conjunction with a specially marked roll, giving correct interpretation of tempo.

I, is channel leading to primary pneumatic J operating secondary pneumatic K, which exhausts striking motor L, connected to key lever M to depress piano key.

The themodist device consists of two small holes, one at each end of tracker bar E, connecting with pneumatic valve, which increases power of suction instantaneously when melody notes are being played, by means of an extra perforation at each outside edge of music roll D; one hole for bass melody at left, and one at right edge for treble melody.

N, is metal arm or bracket connected to lever in front for purpose of depressing sustaining pedal of piano.

O, is the governing bellows of motor for operating music-roll and prevents pace of roll being accelerated or retarded by hard or soft pedalling, thus allowing great change of expression to be made without interfering with speed of roll.

Mechanical Playing.

The most expert performers are now rivalled technically by the recent extraordinary invasion of the American automatic piano-players—the Angelus, Pianola, Apollo, Cecilian, and other varieties of the same idea. The use of the perforated roll acts by means of the ingenious and indeed faultless application of pneumatic leverage to the ordinary piano, doing duty for the pianist's fingers; and it is made possible to play louder or softer, faster or slower, by mechanical arrangement. Such an instrument lacks the player's touch, which is as personal and indispensable for sympathy as the singer's voice or violinist's bow. Still, to a violinist, it is a benefit to have a correct coadjutor in a Beethoven or Brahms sonata with one of these handy companions, just as it is to a singer to have always at command the accompaniments to his or her repertory. The Apollo has the addition of a useful transposing apparatus—an aid, however, that, though often tried, has never yet been adopted; it is possibly too disturbing to the musician's ear. The mechanical tuning-pin is an analogous experiment which comes regularly under notice as the years go by, to be as persistently rejected. The most practical of these tuning inventions was the Alibert, shown in the Inventions Exhibition, 1885. Here, pressure upon the strings above the wrest-plank bridge modified their tension after a first rough adjustment to pitch had been effected.

The perforated music-sheet, a mechanism common to piano-playing attachments as well as self-playing pianos, first appears in a French patent, 1842. A United States patent for a keyboard piano-player was issued to E. D. Bootman (Dec. 18, 1860), and the first pneumatic keyboard piano-player was patented in France in 1863 by M. Fourneaux. Between 1879 and 1902 a total of 55 patents had been issued in the States. The first complete automatic piano-player ready for performance was the Angelus (No. 24799, 1897). The specification is from a communication to the British patent office by Edward Hollingworth White, of Meriden, New Haven county, Conn., U.S.A. There is a pneumatic chest, fulcrum bar, finger levers, bellows and pedals. The whole apparatus is contained in a portable cabinet mounted upon castors, so as to be conveniently moved about a room. The finger levers or key strikers correspond with a considerable portion of the manual keys or clavier of a piano. Thus the automatic piano-player comprises a portable cabinet provided with bellows and operating pedals, a pneumatic actuating mechanism, a tracker adjusted for the use of a perforated music-sheet, a pneumatic motor and winding-roll mechanism to propel the music-sheet, and a series of finger levers operated by the pneumatic mechanism, so projecting as to overhang the piano keyboard and play upon it, with rockers or levers for depressing the piano pedals. Subsequently the apparatus was made capable of accelerating or retarding the tempo at the will of the operator. A roll of music, 12 in. wide and varying in length according to the composition, can be placed in position promptly, and when exhausted can be returned upon its original roll by a simple stop, altogether a triumph of mechanical adjustment. The Pianola followed in 1898, the Apollo 1900. The difference of all these clever contrivances is not conspicuous to the amateur.

While these allied inventions have had to do with a substitute for touch and the necessity for the persevering acquirement of a difficult technique, another, the Virgil Practice Clavier, so called after the inventor, Mr Almon Kincaid Virgil, an American music teacher, is intended to shorten the period of study by doing away with tone, so that the finger technique is acquired mechanically and unmusically, while value of tone, reading, expression, whatever we understand by musical production exciting our receptivity through the ear, is delayed until the player's hand is formed and considerably developed. The opinion of some of the very greatest pianists is brought forward as approving of the system; in the work, for instance, of Vladimir de Pachmann, whose technique was formed long before the Virgil Clavier came to Europe. Bearing in mind that the minimum weight of the touch of a concert piano is not likely to exceed three and a half ounces it is hardly likely that these skilled performers use this dumb keyboard with the graduated weight advised for advancing

pupils, namely, from five to eight ounces. It is allowed that the lightest possible touch may be used at first. One high recommendation certainly remains after all that may be said regarding Mr Virgil's invention: that it is practically silent, almost noiseless, the up and down clicks that mark the duration of finger attachment being alone audible, a boon to the unwilling hearers of ordinary piano practice, scales and five-fingor exercises. Mr Virgil's invention was produced in its elementary form in 1872, the more satisfactory Practice Clavier dates from the completion of the invention, about 1890. It was brought to England in 1895 by Mr Virgil.

The Dumb Keyboard.

PIANOSA (anc. *Planasia*), an island of Italy, belonging to the province of Leghorn, and forming part of the commune of Marciana (Elba), from which it is 7½ m. S.W. Pop. (1881), 774. As its name indicates, it is quite flat, and the highest point is only 95 ft. above sea-level. Its area is 6 sq. m. Augustus banished to it his grandson, Agrippa Postumus, and some ruins of baths near the harbour still bear his name. It changed hands more than once in the wars between Pisa and Genoa in the 12th and 13th centuries; from 1390 it belonged to the prince of Piombino, but was depopulated in 1553 by the Turkish fleet, and only resettled at the beginning of the 19th century. In 1857 a penal colony was established here.

PIARISTS, the popular name of a Catholic educational order, the "clerici regulares scholarum *piarum*," the Pauline Congregation of the Mother of God, founded by Joseph Calasanza (Josephus a Matre Dei) at Rome in the beginning of the 17th century. Calasanza, a native of Calasanz in the province of Huesca in Aragon, was born on the 11th of September 1556, studied at Lerida and Alcalá, and after his ordination to the priesthood removed to Rome (1592). Here he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent Congregation, numbering at that time fifteen priests, under Calasanza as their head. To the three usual vows they added a fourth, that of devotion to the gratuitous instruction of youth. In 1622 the Congregation received a new constitution from Gregory XV., and had all the privileges of the mendicant orders conferred upon it, Calasanza being recognized as general. In 1643 the jealousy of the Jesuits led to his removal from office; owing to the same cause the Congregation was deprived of its privileges by Innocent X. in 1646. Calasanza, who died on the 22nd of August 1648, was beatified in 1748, and canonized in 1767. The privileges of the Congregation were successively restored in 1660, 1669 and 1698. The Piarists, who are not numerous, are found chiefly in Italy, Spain, the West Indies, Germany, and especially in Austria-Hungary. Before the course of study was regulated by the state, a Piarist establishment contained nine classes: reading, writing, elementary mathematics, schola parva or Rudimentorum, schola Principiorum, Grammatica, Syntaxis, Humanitas or Poesis, Rhetorica. The general provost of the order is chosen by the general chapter, and with a general procurator and four assistants resides at Rome. The members are divided into professors, novices, and lay brethren. Their dress is very similar to that of the Jesuits; their motto "Ad majus pietatis incrementum!"

For Calasanza, see Timon-David, *Vie de St Joseph Calasance* (Marseilles, 1884); on the Piarists, P, Helyot, *Hist. des ordres religieuses* (1715), iv. 281; J. A. Seyffert, *Ordensregeln der Piaristen* (Halle, 1783); J. Schaller, *Gedanken über die Ordensfassung der Piaristen* (Prague, 1805); A. Heimbucher, *Orden und Kongregationen* (1897), ii. 271; articles by O. Zöckler in Herzog-Hauck's *Realencyklopädie für protestantische Theologie* (1904), vol. xv. and by C. Kniel in Wetzer and Welte's *Kirchen-lexikon* (1895), vol. ix.

PIATRA (Peatra), the capital of the department of Neamtzu, Rumania, situated on the left bank of the river Bistritza, where it cuts a way through the Carpathian foothills. Pop. (1900), 17,391. A branch railway passes through the town, and at Bacau meets the main line from Czernowitz in Bukowina to Galatz. The church of St John's (or the Prince's) monastery was founded in 1497 by Stephen the Great. There are saw-mills and textile factories in Piatra, which has a considerable trade in wine and timber. Neamtzu is one of the most densely forested regions in Moldavia. Lumber rafts are floated down the Bistritza to the Sereth, and so on to Galatz. There are several monasteries in the neighbourhood.

PIATTI, CARLO ALFREDO (1822–1901), Italian violoncellist, was born at Bergamo on the 8th of January 1822. He was the son of a violinist, and became a pupil at the conservatorio of Milan. From 1838 onwards he journeyed over Europe, playing with extraordinary success in all the important cities of the Continent. In 1844 he appeared before the London public at a Philharmonic Concert; and in 1859, on the foundation of the Popular Concerts, he took up the work with which he was most intimately connected for thirty-nine seasons, retaining until 1897 the post of first violoncello at these famous chamber concerts, during the latter

half of each series. His purely classical style, his wide musical sympathies, and his general culture and charm, would have ensured him a high position even without his marvellously finished technical skill. In 1894 the fiftieth anniversary of his first appearance in London was celebrated by a reception given in honour of him and his lifelong friend Joachim. He retired from public life, owing to a severe illness, in 1897, and until his death at Bergamo on the 19th of July 1901 divided his time between his native town and Cadenabbia. As a composer he attained a wide popularity with some graceful and popular songs; he did excellent work as an editor; and he was an enthusiastic collector and musical antiquary.

PIAUHY, or PIAUHI, a north-eastern state of Brazil, bounded N. and W. by Maranhão, E. by Ceará, Pernambuco and Bahia, and S. by Bahia. It has a few miles of Atlantic coast-line on the N., and the Rio Parnahyba forms the boundary line with Maranhão throughout its entire length. Area, 116,523 sq. m.; pop. (1900), 334,328. Part of the state on the Atlantic coast and along the lower Parnahyba is low, swampy and malarial. South of this the country rises gradually to a high plateau with open campos. This plateau region is watered by numerous tributaries of the Parnahyba, chief of which are the Urussuhy, the Canindé and its tributary the Piauhy, the Gurgucia and its tributary the Parahim, which drains the large inland lake of Parnaguá, the Longa, and the Poty, which has its source in the state of Ceará. The Parnahyba is navigable for boats of 3 ft. draught up to Nova York, a few miles above the mouth of the Gurgueia, and could be made navigable up to the mouth of the Balsas. The climate is hot and humid in the lowlands and along the lower Parnahyba, but in the uplands it is dry with high sun temperatures and cool nights. The principal industry is stock-raising, which dates from the first settlement in 1674 by Domingos Affonso Mafrense, who established here a large number of cattle ranges. A secondary industry is the raising of goats, which are able to stand neglect and a scanty food supply. Sheep have likewise been raised in Piauhy, but there is no market for mutton and their wool is not utilized. The agricultural products are cotton, sugar and tobacco. Of food-stuffs the people do not produce enough for their own consumption. Forest products include rubber, carnauba wax and dyewoods. The exports include hides, skins, rubber, wax, tobacco and cotton. The capital is Therezina, on the right bank of the Parnahyba, 250 m. above Parnahyba (town), with which it is connected by a line of light-draught river-boats. The town dates from 1852, is attractively situated, and is regularly laid out with broad, straight streets crossing each other at right angles. The population of the *municipio* in 1890 was 31,523, which includes a large rural district. Other towns, with their populations in 1890, are Oeiras (19,858), founded in 1718 under the name of Moxa; Amarante (15,525); Valença (17,693); and Campo Maior (12,425), the figures given of population being those of the large districts (*municipios*) in which the towns are situated.

PIAZZA, properly an open square or place in an Italian town (Ital. *piazza*, from Lat. *platea*, broad space, Gr. πλάτυς, broad). These squares were usually surrounded with a colonnade or arcade, and thus the word has been loosely applied to a covered walk or arcade along the front of a building, and in America, to the veranda of a house.

PIAZZA ARMERINA, a city of Sicily, in the province of Caltanisetta, 39 m. by road E.S.E. from that town, and the same distance S. of the railway station of Assoro-Valguarnera, 43 m. W. of Catania, situated 2360 ft. above sea-level. Pop. (1901), 24,119. It has a 15th-century cathedral, with a fine campanile, and some of the houses show Norman or Gothic architecture. The foundation of the town dates from the 11th century, and the dialect is Lombard.

See Mauceri in *L'Arte* (1906), 14.

PIAZZI, GIUSEPPE (1746–1826), Italian astronomer, was born at Ponte, in the Valtellina, on the 16th of July 1746. He entered the Theatine Order in 1764, accepted the chair of mathematics in the academy of Palermo in 1780, and persuaded the viceroy, Prince Caramanico, to build an observatory there. During a visit to England in 1788 he procured from Jesse Ramsden a 5-ft. altazimuth, with which he collected at Palermo, 1792–1813, the materials for two admirable star-catalogues, published in 1803 and 1814 respectively. While engaged on this work he discovered, on the 1st of January 1801, the first asteroid or minor planet, to which he gave the name of Ceres, the tutelary deity of Sicily. He died at Naples on the 22nd of July 1826.

Jahrbuch*, liv. 218; *Bulletin des sciences* (1826), vi. 339; *Edin. Journal of Science* (1827), vi. 193; *Memoirs Roy. Astr. Soc.* iii. 119; R. Grant, *Hist. Phys. Astronomy*, pp. 238, 510, 549.

PIBRAC, GUY DU FAUR, SEIGNEUR DE (1529–1584), French jurist and poet, was born at Toulouse, of an old family of the magistracy. He studied law there with Jacques Cujas, and afterwards at Padua. In 1548 he was admitted to the bar at Toulouse, at once took high rank, and rose to be *juge-mage*, an office in Languedocian cities about equal to that of *prévôt*. He was selected in 1562 as one of the three representatives of the king of France at the Council of Trent. In 1565 he became general advocate to the parlement of Paris, and extended the renaissance in jurisprudence which was transforming French justice. In 1573 he was sent by Charles IX. to accompany as chancellor his brother Henry (afterwards Henry III.) to Poland, of which country Henry had been elected king. Pibrac's fluent Latin won much applause from the Poles, but his second visit to Poland in 1575, when sent back by Henry III. to try to save the crown he had deserted, was not so successful. Then he was employed in negotiations with the so-called *politiques*, and he managed to keep them quiet for a while. In 1578 he became the chancellor of Marguerite of France, queen of Navarre. Although he was fifty, her beauty and intellectual gifts led him to aspire to win her affection; but he was rejected with disdain. He died in 1584. His oratorical style was too pedantic, but quotations from the classics had a fresher meaning in his day. He was the friend of Ronsard, de Thou and L'Hôpital, and left, among other literary remains, elegant and sententious *quatraines*.

PIBROCH, a form of music as played by the bagpipe. The word is derived from the Gaelic *piobaireachd*, the art of the bagpiper. This special form of bagpipe music, consisting of a series of variations founded on a theme, was called the *urlar*. These variations are generally of a martial or warlike character and include dirges and marches (see BAGPIPE).

PICA, the name of the European representative of a group of diminutive rodent mammals, also known as tailless hares, mouse-hares, or piping hares, constituting the family *Ochotonidae* with the single genus *Ochotona*. From the more typical hares and rabbits they differ by the short and rounded ears, the absence of a tail, and the relatively shorter hind-limbs, as well as by complete collar-bones. The soles of the feet are hairy, and the fur is usually soft and thick; while in some cases the last upper molar is absent. Picas are inhabitants of cold and desert regions. They dwell either in the chinks between rocks, or in burrows, although one Himalayan species frequents pine-forests. They are very active, and most of the species utter a piping or whistling cry. They store up a supply of grass for winter use; in Siberia it is stacked in small heaps. The Himalayan *Ochotona roylei* may be seen in the daytime, but most kinds are nocturnal. The Siberian species, *O. alpina*, ranges into eastern Europe, but Central Asia is the headquarters, although a few species range into Arctic America and the Rocky Mountains. In size picas may be compared to guinea-pigs. Till of late years the group has been generally known by the name of *Lagomys*. There are several extinct genera.

See RODENTIA; also J. L. Bouhote, "The Mouse-hares of the genus *Ochotona*," *Proc. Zool. Soc.* (London, 1905). (R. L.*)

PICA, the Latin name of a genus of oscine passerine birds, the magpies. The Latin word, by interchange of initial *p* and *k*, is possibly the Gr. κίσσα (see MAGPIE), and probably the same word as *picus*, the woodpecker (*q.v.*). Another derivation would connect both *pica* and *picus* with the root *pic-* of *pingere*, to

pupils, namely, from five to eight ounces. It is allowed that the lightest possible touch may be used at first. One high recommendation certainly remains after all that may be said regarding Mr Virgil's invention: that it is practically silent, almost noiseless, the up and down clicks that mark the duration of finger attachment being alone audible, a boon to the unwilling hearers of ordinary piano practice, scales and five-fingor exercises. Mr Virgil's invention was produced in its elementary form in 1872, the more satisfactory Practice Clavier dates from the completion of the invention, about 1890. It was brought to England in 1895 by Mr Virgil.

The Dumb Keyboard.

PIANOSA (anc. *Planasia*), an island of Italy, belonging to the province of Leghorn, and forming part of the commune of Marciana (Elba), from which it is 7½ m. S.W. Pop. (1881), 774. As its name indicates, it is quite flat, and the highest point is only 95 ft. above sea-level. Its area is 6 sq. m. Augustus banished to it his grandson, Agrippa Postumus, and some ruins of baths near the harbour still bear his name. It changed hands more than once in the wars between Pisa and Genoa in the 12th and 13th centuries; from 1390 it belonged to the prince of Piombino, but was depopulated in 1553 by the Turkish fleet, and only resettled at the beginning of the 19th century. In 1857 a penal colony was established here.

PIARISTS, the popular name of a Catholic educational order, the "clerici regulares scholarum *piarum*," the Pauline Congregation of the Mother of God, founded by Joseph Calasanza (Josephus a Matre Dei) at Rome in the beginning of the 17th century. Calasanza, a native of Calasanz in the province of Huesca in Aragon, was born on the 11th of September 1556, studied at Lerida and Alcalá, and after his ordination to the priesthood removed to Rome (1592). Here he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent Congregation, numbering at that time fifteen priests, under Calasanza as their head. To the three usual vows they added a fourth, that of devotion to the gratuitous instruction of youth. In 1622 the Congregation received a new constitution from Gregory XV., and had all the privileges of the mendicant orders conferred upon it, Calasanza being recognized as general. In 1643 the jealousy of the Jesuits led to his removal from office; owing to the same cause the Congregation was deprived of its privileges by Innocent X. in 1646. Calasanza, who died on the 22nd of August 1648, was beatified in 1748, and canonized in 1767. The privileges of the Congregation were successively restored in 1660, 1669 and 1698. The Piarists, who are not numerous, are found chiefly in Italy, Spain, the West Indies, Germany, and especially in Austria-Hungary. Before the course of study was regulated by the state, a Piarist establishment contained nine classes: reading, writing, elementary mathematics, schola parva or Rudimentorum, schola Principiorum, Grammatica, Syntaxis, Humanitas or Poesis, Rhetorica. The general provost of the order is chosen by the general chapter, and with a general procurator and four assistants resides at Rome. The members are divided into professors, novices, and lay brethren. Their dress is very similar to that of the Jesuits; their motto "Ad majus pietatis incrementum!"

For Calasanza, see Timon-David, *Vie de St Joseph Calasance* (Marseilles, 1884); on the Piarists, P. Helyot, *Hist. des ordres religieuses* (1715), iv. 281; J. A. Seyffert, *Ordensregeln der Piaristen* (Halle, 1783); J. Schaller, *Gedanken über die Ordensfassung der Piaristen* (Prague, 1805); A. Heimbucher, *Orden und Kongregationen* (1897), ii. 271; articles by O. Zöckler in Herzog-Hauck's *Realencyklopädie für protestantische Theologie* (1904), vol. xv. and by C. Kniel in Wetzer and Welte's *Kirchen-lexikon* (1895), vol. ix.

PIATRA (PEATRA), the capital of the department of Neamtzu, Rumania, situated on the left bank of the river Bistritza, where it cuts a way through the Carpathian foothills. Pop. (1900), 17,391. A branch railway passes through the town, and at Bacau meets the main line from Czernowitz in Bukowina to Galatz. The church of St John's (or the Prince's) monastery was founded in 1497 by Stephen the Great. There are saw-mills and textile factories in Piatra, which has a considerable trade in wine and timber. Neamtzu is one of the most densely forested regions in Moldavia. Lumber rafts are floated down the Bistritza to the Sereth, and so on to Galatz. There are several monasteries in the neighbourhood.

PIATTI, CARLO ALFREDO (1822–1901), Italian violoncellist, was born at Bergamo on the 8th of January 1822. He was the son of a violinist, and became a pupil at the conservatorio of Milan. From 1838 onwards he journeyed over Europe, playing with extraordinary success in all the important cities of the Continent. In 1844 he appeared before the London public at a Philharmonic Concert; and in 1859, on the foundation of the Popular Concerts, he took up the work with which he was most intimately connected for thirty-nine seasons, retaining until 1897 the post of first violoncello at these famous chamber concerts, during the latter

clergy; in the second part the hero is presented as a devout youth transformed into a tunny at the intercession of the Virgin Mary, who thus saved him from death; after many extravagant experiences in this form he is restored to human shape, and proposes to teach the submarine language at the university of Salamanca. This dull performance naturally failed to please and, meanwhile, many surreptitious copies of the first part were introduced into Spain; the Inquisition finally gave up the attempt to suppress it, and in 1573 an expurgated edition was authorized. With this mutilated version the Spanish public was forced to be content during the remaining fifteen years of Philip II.'s reign. Upon the death of this sombre monarch society relaxed its hypocritical pose of austerity, and in 1599 Mateo Alemán (*q.v.*) published the *Primera parte de Guzmán de Alfarache*. It is modelled upon *Lazarillo de Tormes*, being the autobiography of the son of a ruined Genoese money-lender; but the writer indulges in a tedious series of moralizings. This contrasts sharply with the laconic cynicism of *Lazarillo de Tormes*; but *Guzmán de Alfarache* is richer in invention, in variety of episode and in the presentation of character. Its extraordinary popularity tempted a Valencian lawyer named Juan José Martí to publish a *Segunda parte de la vida del pícaro Guzmán de Alfarache* (1602) under the pseudonym of Mateo Luján de Sayavedra. Though partly plagiarized from the manuscript of the genuine second part to which Martí had somehow obtained access, the continuation was coldly received; in 1604 Alemán brought out the true continuation, and revenged himself by introducing into the narrative a brother of Martí—a crazy picaroon of the lowest morality, who ultimately commits suicide in disgust at his own turpitude. In *Lazarillo de Tormes*, and still more in *Guzmán de Alfarache*, it is difficult to distinguish between the invented episodes and the personal reminiscences of the authors. The *Viage entretenido* (1603) of Agustín de Rojas is a realistic account of the writer's experiences as a strolling actor and playwright, and, apart from its considerable literary merits, it is an invaluable contribution to the history of the Spanish stage as well as a graphic record of contemporary low life; the chief character in the book is called the *caballero del milagro*, an expression which recurs in Spanish literature as the equivalent of a *chevalier d'industrie*.

The next in chronological order of the Spanish picaresque tales is *La Pícara Justina* (1605), the history of a woman picaroon, which it has long been customary to ascribe to Andrés Pérez, a Dominican monk; there is, however, no good reason to suppose that the name of Francisco López de Úbeda on the title-page is a pseudonym. The *Pícara Justina* has wrongly acquired a reputation for indecency; its real defects are an affected diction and a want of originality. The writer frankly admits that he has taken material from the *Celestina*, from *Lazarillo de Tormes*, from Guevara, Timoneda and Alemán, and he boastfully asserts that "there is nothing good in ballad, play or Spanish poet, but that its quintessence is given here." Unluckily he has not the talent to utilize these stolen goods. The *Pícara Justina* was thrice reprinted during the 17th century; this is the only basis for the untenable theory that it is the source of the *culteranismo* which reaches its climax in Gracian's treatises. The *Pícara Justina* is now read solely by philologists in quest of verbal eccentricities. Ginés de Pasamonte, one of the secondary figures in *Don Quixote* (1605–1615), is a singularly vivid sketch of the Spanish rogue, and in the comedy entitled *Pedro de Urdemalas* Cervantes again presents a brilliant panorama of picaresque existence. He returns to the subject in *Rinconete y Cortadillo* and in the *Coloquio de los perros*, two of the best stories in the *Novelas ejemplares* (1613). The attraction of picaresque life was felt by pious and learned critics, and expounded in print. In the *Viage del mundo* (1614) the zealous missionary Pedro de Cevallos interpolates amusing tales of what befell him in the slums of Andalusia before he fled from justice to America, where he lived as a sinful soldier till his spiritual conversion was accomplished. Cristóbal Suárez de Figueroa, a caustic critic of his contemporaries and an arbiter of taste, did not think it beneath his dignity to show a disconcerting acquaintance with the ways of professional rogues, and in *El Pasagero* (1617) he fills in the sketch of the knavish innkeeper already outlined by Cervantes in *Don Quixote*. Evidence of the widely diffused taste for picaresque literature is found in *Enriquez de Castro* (1617), an interminable story written in Spanish by a Frenchman named François Loubayssin de Lamarca, who brought out his book at Paris; two years previously Loubayssin had introduced some clever but risky picaresque episodes in his *Engaños deste siglo y historia sucedida en nuestros tiempos*. But his attempt to fill a larger canvas is a complete failure.

The roving instinct of Vicente Martínez Espinel (*q.v.*) had led him into strange and dangerous company before and after his ordination as a priest, and a great part of his *Relaciones de la vida del escudero Marcos de Obregón* (1618) is manifestly the confession of one who has regretfully outlived his pleasant vices. The baffling compound of fact with fiction and the lucid style of which Espinel was a master would suffice to win for *Marcos de Obregón* a permanent place in the history of Spanish literature; the fact that it was largely utilized by Le Sage in *Gil Blas* has won for it a place in the history of comparative literature. Within five months of its publication at Madrid a fragmentary French version by the sieur d'Audiguier was issued at Paris, and at Paris also there appeared a Spanish picaresque story entitled *La Desordenada codicia de los bienes ajenos* (1619), ascribed conjecturally to a certain Dr Carlos García, who reports his conversation with a garrulous gaol-bird, and appends a glossary of slang terms used by the confraternity of thieves; he was not, however, the first worker in this field, for a key to their gross jargon had been given ten years previously by Juan Hidalgo in his *Romances de germania* (1609), a series of gipsy ballads. Every kind of picaroon is portrayed with intelligent sympathy by Alonso Jerónimo de Salas Barbadillo, who is always described as a picaresque novelist; yet he so constantly neglects the recognized conventions of the Spanish school that his right to the title is disputable. Thus in *La Hija de Celestina* (1612) he abandons the autobiographical form, in *El Subtil cordobés Pedro de Urdemalas* (1620) he alternates between dialogue and verse, and in *El Necio bien afortunado* (1621) the chief character is rather a cunning dolt than a successful scoundrel. The pretence of warning newcomers against the innumerable occasions of sin in the capital is solemnly kept up by Antonio Liñan y Verdugo in his *Guia y avisos de forasteros que vienen á la corte* (1620), but in most of his tales there is more entertainment than decorum.

The profession of a serious moral purpose on the part of many picaresque writers is often a transparent excuse for the introduction of unsavoury incident. There is, however, no ground for doubting the sincerity of the physician Jerónimo de Alcalá Yañez y Ribera, who at one time thought of taking holy orders, and studied theology under St John of the Cross. An unusual gravity of intention is visible in *Alonso, mozo de muchos amos* (1624–1626), in which the repentant *pícaro* Alonso, now a lay-brother, tells the story of his past life to the superior of the monastery in which he has taken refuge. It abounds with pointed anecdotes and with curious information concerning the Spanish gipsies, and this last characteristic explains George Borrow's hyperbolical praise of the work as competing with *Don Quixote* in grave humour, and as unequalled "for knowledge of the human mind and acute observation."

At about this time there lived in Spain an ex-nun named Catalina de Erauso, who fled from her convent, dressed herself in men's clothes, enlisted, was promoted ensign, and saw more of life than any other nun in history. Broadsides relating the story of this picaresque amazon were circulated during her lifetime, and the details of her adventures arrested the attention of De Quincey, who would seem to have read them in a Spanish original which has been admirably translated since then by the French poet José Maria de Heredia. This Spanish original, in its existing form, was issued no earlier than 1829 by Joaquín María de Ferrer, whose character is not a satisfactory guarantee of the work's authenticity; but its interest is unquestionable. No such suspicion attaches to the *Vida* of Alonso de Contreras, first published in 1899; this out-at-elbows soldier faithfully records how he became a knight of the Order of Santiago, how he

pupils, namely, from five to eight ounces. It is allowed that the lightest possible touch may be used at first. One high recommendation certainly remains after all that may be said regarding Mr Virgil's invention: that it is practically silent, almost noiseless, the up and down clicks that mark the duration of finger attachment being alone audible, a boon to the unwilling hearers of ordinary piano practice, scales and five-finger exercises. Mr Virgil's invention was produced in its elementary form in 1872, the more satisfactory Practice Clavier dates from the completion of the invention, about 1890. It was brought to England in 1895 by Mr Virgil.

PIANOSA (anc. *Planasia*), an island of Italy, belonging to the province of Leghorn, and forming part of the commune of Marciana (Elba), from which it is 7½ m. S.W. Pop. (1881), 774. As its name indicates, it is quite flat, and the highest point is only 95 ft. above sea-level. Its area is 6 sq. m. Augustus banished to it his grandson, Agrippa Postumus, and some ruins of baths near the harbour still bear his name. It changed hands more than once in the wars between Pisa and Genoa in the 12th and 13th centuries; from 1390 it belonged to the prince of Piombino, but was depopulated in 1553 by the Turkish fleet, and only resettled at the beginning of the 19th century. In 1857 a penal colony was established here.

PIARISTS, the popular name of a Catholic educational order, the "clerici regulares scholarum *piarum*," the Pauline Congregation of the Mother of God, founded by Joseph Calasanza (Josephus a Matre Dei) at Rome in the beginning of the 17th century. Calasanza, a native of Calasanz in the province of Huesca in Aragon, was born on the 11th of September 1556, studied at Lerida and Alcalá, and after his ordination to the priesthood removed to Rome (1592). Here he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent Congregation, numbering at that time fifteen priests, under Calasanza as their head. To the three usual vows they added a fourth, that of devotion to the gratuitous instruction of youth. In 1622 the Congregation received a new constitution from Gregory XV., and had all the privileges of the mendicant orders conferred upon it, Calasanza being recognized as general. In 1643 the jealousy of the Jesuits led to his removal from office; owing to the same cause the Congregation was deprived of its privileges by Innocent X. in 1646. Calasanza, who died on the 22nd of August 1648, was beatified in 1748, and canonized in 1767. The privileges of the Congregation were successively restored in 1660, 1669 and 1698. The Piarists, who are not numerous, are found chiefly in Italy, Spain, the West Indies, Germany, and especially in Austria-Hungary. Before the course of study was regulated by the state, a Piarist establishment contained nine classes: reading, writing, elementary mathematics, schola parva or Rudimentorum, schola Principiorum, Grammatica, Syntaxis, Humanitas or Poesis, Rhetorica. The general provost of the order is chosen by the general chapter, and with a general procurator and four assistants resides at Rome. The members are divided into professors, novices, and lay brethren. Their dress is very similar to that of the Jesuits; their motto "Ad majus pietatis incrementum!"

For Calasanza, see Timon-David, *Vie de St Joseph Calasance* (Marseilles, 1884); on the Piarists, P. Helyot, *Hist. des ordres religieuses* (1715), iv. 281; J. A. Seyffert, *Ordensregeln der Piaristen* (Halle, 1783); J. Schaller, *Gedanken über die Ordensfassung der Piaristen* (Prague, 1805); A. Heimbucher, *Orden und Kongregationen* (1897), ii. 271; articles by O. Zöckler in Herzog-Hauck's *Realencyklopädie für protestantische Theologie* (1904), vol. xv. and by C. Kniel in Wetzer and Welte's *Kirchen-lexikon* (1895), vol. ix.

PIATRA (Peatra), the capital of the department of Neamtzu, Rumania, situated on the left bank of the river Bistritza, where it cuts a way through the Carpathian foothills. Pop. (1900), 17,391. A branch railway passes through the town, and at Bacau meets the main line from Czernowitz in Bukowina to Galatz. The church of St John's (or the Prince's) monastery was founded in 1497 by Stephen the Great. There are saw-mills and textile factories in Piatra, which has a considerable trade in wine and timber. Neamtzu is one of the most densely forested regions in Moldavia. Lumber rafts are floated down the Bistritza to the Sereth, and so on to Galatz. There are several monasteries in the neighbourhood.

PIATTI, CARLO ALFREDO (1822–1901), Italian violoncellist, was born at Bergamo on the 8th of January 1822. He was the son of a violinist, and became a pupil at the conservatorio of Milan. From 1838 onwards he journeyed over Europe, playing with extraordinary success in all the important cities of the Continent. In 1844 he appeared before the London public at a Philharmonic Concert; and in 1859, on the foundation of the Popular Concerts, he took up the work with which he was most intimately connected for thirty-nine seasons, retaining until 1897 the post of first violoncello at these famous chamber concerts, during the latter

development. The same may be said of Portugal; for though Silva Cabral's continuation of the *Bachiller Trapaza* is called the most remarkable of Portuguese picaresque romances, it is significant that *O peralvilho de Cordova* remains in manuscript.

The case was very different in France, where pictures of low life had always found admirers. The first translation of *Lazarillo de Tormes* appeared, as already noted, at Paris in 1561; the first translation of the first part of *Guzmán de Alfarache* was issued there by Gabriel Chappuis in 1600, and the dictator Chapelain deigned to translate both parts in 1619-1620; the first translation of the *Novelas ejemplares* was published at Paris in 1618 by Rosset and d'Audiguier; and French translations of *Marcos de Obregón*, of *La Desordenada codicia*, of the *Buscón* and of the *Pícara Justina* were printed in 1618, 1621, 1633 and 1635 respectively. Before this series of translations was completed Charles Sorel recounted in *Francion* (1622) "the comic mishaps which befall evil-doers," invoking the common excuse that it is "lawful to find pleasure at their expense." Many of the episodes in *Francion* are picaresque in tone, but unfortunately Sorel wanders from his subject, and devotes no small part of his book to satirizing literary men who, though fribbles or paupers, are in no sense picaroons. The legitimate Spanish tradition is followed more closely and with much more ability by Paul Scarron in the *Roman comique* (1651), in which horseplay is predominant. The framework may have been suggested by Agustín de Rojas or Quevedo, both of whom introduce a strolling company, and such characters as Liandre, Angélique de l'Etoile and Ragotin might be found in any average *novela picaresca*. Scarron frankly mentions Castillo Solórzano's *Garduña de Sevilla* in his text, and his *Précaution inutile* and *Les Hypocrites* are convincing proofs of close study of Spanish picaresque stories: the *Précaution inutile* is taken from *Guzmán de Alfarache*, and *Les Hypocrites* is merely a translation of Salas Barbadillo's *Hija de Celestina*. The *Roman bourgeois* (1666) of Antoine Furetière is generally described as a picaresque novel, but this involves a new definition of the adjective; the *Roman bourgeois* includes some portraits and more satire which seem suggested by picaresque reading, but it is concerned with the foibles of the middle class rather than with the sly devices of common vagabonds.

The Spanish picaroon lives again in *Gil Blas*, where, with a dexterity almost rarer than original genius, a master of literary manipulation fuses materials unearthed from forgotten and seemingly worthless Spanish quarries. Gil Blas is a creation of the gentler, sunnier French spirit; like Beaumarchais' Figaro he is a Spaniard born, reared and humanized in Paris, and these two are the only picaroons whose relative refinement has not been gained at the cost of verisimilitude. But the old original scoundrel was not yet extinct: in the interval between the appearance of the *Barbier de Séville* and the *Mariage de Figaro* Restif de la Bretonne produced a sequel (1776) to the *Buscón*—a sequel so dull as to be wellnigh unreadable. The untamed Spanish rogue had become impossible towards the end of the 18th century: in the 19th he was deliberately rejected when Théophile Gautier wrote his *Capitaine Fracasse*. Yet Gautier conscientiously provides a Spanish atmosphere; the personage have Spanish names; the knife has a Spanish inscription; the host speaks French with a Spanish accent; Vallombreuse parts from the marquis with a Spanish formula: "beso á vuestra merced la mano, caballero." *Capitaine Fracasse* is the last important book which continues the picaresque tradition. The possibilities of picaresque fiction can never be exhausted while human nature is unchanged. Pereda (*q.v.*) in *Pedro Sánchez* (1884) touches the old theme with the accent of modernity. It may be that instead of one continuous tale, interrupted by episodical digressions, the picaresque fiction of the future will take the form of short stories independent of one another; but this would be nothing more than a convenient mechanical device, a readjustment of means to ends.

PICAYUNE, the name in Florida and Louisiana of the Spanish half-real, $=\frac{1}{16}$ of a dollar, $6\frac{1}{4}$ cents, and hence used of the United States 5-cent piece. The French *picaillon*, from which the word was adapted in America, was an old copper coin of Piedmont. Its origin is doubtful, but is possibly related to the Italian *piccolo*, little, small. In America the word is used of anything trifling, petty, mean or contemptible.

PICCANINNY, or PICKANINNY, a word applied originally by the negroes of the West Indies to their babies. It is adapted either from Span. *pequeño*, small, or Port. *pequenino*, very small. The word spread with the slave trade to America, and has since been adopted in Australia and in South Africa.

PICCININO, NICCOLÒ (1386–1444), Italian *condottiere*, born at Perugia, was the son of a butcher. He began his military career in the service of Braccio da Montone, who at that time was waging war against Perugia on his own account, and at the death of his chief, shortly followed by that of the latter's son Oddo, Piccinino became leader of Braccio's *condotta*. After serving for a short period under the Florentine Republic, he went over to Filippo Maria Visconti, duke of Milan (1425), in whose service together with Niccolò Fortebraccio he fought in the wars against the league of Pope Eugenius IV., Venice and Florence. He defeated the papal forces at Castel Bolognese (1434), but another papal army under Francesco Sforza having defeated and killed Fortebraccio at Fiordimonte, Piccinino was left in sole command, and in a series of campaigns against Sforza he seized a number of cities in Romagna by treachery. In 1439 he again fought in Lombardy with varying success against Sforza, who had now entered the Venetian service. Piccinino then induced the duke of Milan to send him to Umbria, where he hoped, like so many other *condottieri*, to carve out a dominion for himself. He was defeated by Sforza at Anghiari (1440), but although a number of his men were taken prisoners they were at once liberated, as was usually done in wars waged by soldiers of fortune. Again the war shifted to Lombardy, and Piccinino, having defeated and surrounded Sforza at Martinengo, demanded of the visconti the lordship of Piacenza as the price of Sforza's capture. The duke by way of reply concluded a truce with Sforza; but the latter, who, while professing to defend the Papal States, had established his own power in the Marche, aroused the fears of the pope and the king of Naples, as well as of the visconti, who gave the command of their joint forces to Piccinino. Sforza was driven from the Marche, but defeated Piccinino at Montelauro, and while the latter was preparing for a desperate effort against Sforza he was suddenly recalled to Milan, his army was beaten in his absence, and he died of grief and of his wounds in 1444. Short of stature, lame and in weak health, he was brave to the point of foolhardiness, wonderfully resourceful, and never overwhelmed by defeat. He was cruel and treacherous, and had no aim beyond his own aggrandisement. Piccinino left two sons, Jacopo and Francesco, both distinguished *condottieri*.

A good account of Piccinino is contained in vol. iii. of E. Ricotti's *Storia della compagnie di ventura* (Turin, 1845); G. B. Poggio, *Vita di N. Piccinino* (Venice, 1572); see also the general histories of the period.

PICCINNI, NICCOLA (1728–1800), Italian musical composer, was born at Bari on the 16th of January 1728. He was educated under Leo and Durante, at the Conservatorio di Sant' Onofrio in Naples. For this Piccinni had to thank the intervention of the bishop of Bari, his father, although himself a musician, being opposed to his son's following a musical career. His first opera, *Le Donne dispettose*, was produced in 1755, and in 1760 he composed, at Rome, the *chef d'œuvre* of his early life, *La Cecchina, ossia la buona*

pupils, namely, from five to eight ounces. It is allowed that the lightest possible touch may be used at first. One high recommendation certainly remains after all that may be said regarding Mr Virgil's invention: that it is practically silent, almost noiseless, the up and down clicks that mark the duration of finger attachment being alone audible, a boon to the unwilling hearers of ordinary piano practice, scales and five-fingor exercises. Mr Virgil's invention was produced in its elementary form in 1872, the more satisfactory Practice Clavier dates from the completion of the invention, about 1890. It was brought to England in 1895 by Mr Virgil.

The Dumb Keyboard.

PIATTI, CARLO ALFREDO (1822–1901), Italian violoncellist, was born at Bergamo on the 8th of January 1822. He was the son of a violinist, and became a pupil at the conservatorio of Milan. From 1838 onwards he journeyed over Europe, playing with extraordinary success in all the important cities of the Continent. In 1844 he appeared before the London public at a Philharmonic Concert; and in 1859, on the foundation of the Popular Concerts, he took up the work with which he was most intimately connected for thirty-nine seasons, retaining until 1897 the post of first violoncello at these famous chamber concerts, during the latter

down by the duke, but neither he nor Gallas, the new lieutenant-general of the emperor, possessed the capacity for carrying it out, and the war dragged on year after year. Piccolomini was in 1635 allied with a Spanish army, and bitterly complained that their sloth and caution marred every scheme that he formed. In 1638 he was made a count of the empire, and in 1639, having been fortunate enough to win a great victory over the French (relief of Thionville, July 7, 1639), he was rewarded with the office of privy councillor from the emperor and with the dukedom of Amalfi from the king of Spain. But instead of being appointed, as he hoped, Gallas's successor, he was called in to act as *ad latus* to the Archduke Leopold Wilhelm, with whom he was defeated in the second battle of Breitenfeld in 1642. After this he spent some years in the Spanish service and received as his reward the title of grandee and the order of the Golden Fleece. Some years later, having re-entered the imperial army, he was again disappointed of the chief command by the selection of the brave veteran Peter Melander, Count Holzapfel. But when in 1648 Melander fell in battle at Zusmarshausen, Piccolomini was at last appointed lieutenant-general of the emperor, and thus conducted as generalissimo the final campaign of the weary and desultory Thirty Years' War. Three days after the commission for executing the peace had finished its labours, the emperor addressed a letter of thanks "to the Prince Piccolomini," and awarded him a gift of 114,566 gulden. Piccolomini died on the 11th of August 1656. He left no children (his only son Josef Silvio, the "Max" of Schiller's *Wallenstein*, was murdered by the Swedes after the battle of Jankau in 1645), and his titles and estates passed to his brother's son. With the death of the latter's nephew Octavio Aeneas Josef in 1757, the line became extinct.

PICENE, $C_{22}H_{14}$, a hydrocarbon found in the pitchy residue obtained in the distillation of peat-tar and of petroleum. This is distilled to dryness and the distillate repeatedly recrystallized from cymene. It may be synthetically prepared by the action of anhydrous aluminium chloride on a mixture of naphthalene and ethylene dibromide (R. Lespieau, *Bull. soc. chim.*, 1891, (3), 6, p. 238), or by distilling α-dinaphthostilbene (T. Hirn, *Ber.*, 1899, 32, p. 3341). It crystallizes in large colourless plates which possess a blue fluorescence. It is soluble in concentrated sulphuric acid with a green colour. Chromic acid in glacial acetic acid solution oxidizes it to picene-quinone, picene-quinone carboxylic acid, and finally to phthalic acid. When heated with hydriodic acid and phosphorus it forms hydrides of composition $C_{22}H_{34}$ and $C_{22}H_{36}$ (see E. Bamberger and F. D. Chattaway, *Ann.*, 1895, 284, p. 61).

PICENUM, a district of ancient Italy, situated between the Apennines and the Adriatic, bounded N. by the Senones and S. by the Vestini. The inhabitants were, according to tradition, an offshoot of the Sabines. Strabo (v. 4, 1) gives the story of their migration, led by a woodpecker (*picus*), a bird sacred to Mars, from which they derived their name Picentini (cf. Dion. Hal. i. 14, 5), just as the Hirpini derived theirs from *hirpus*, a wolf. The district was conquered by the Romans early in the 3rd century B.C. and the whole territory was divided up among Latin-speaking settlers by the Lex Flaminia in 232 B.C. Hence we have very scanty records of any non-Latin language that may have been spoken in the district before the 3rd century. Besides the problematic inscriptions from Belmonte, Nereto and Cupra Maritima (see SABELLIC), we have one or two Latin inscriptions (probably of the 2nd or even the 1st century B.C.) which contain certain forms showing a distinct affinity with the dialect of Iguvium (cf. the name *Pašdi* = Latin *Pacidii*). Hence there seems some ground for believing that the population which the Romans dispossessed, or held in subjection, really spoke a dialect very much like that of their neighbours in Umbria.

For inscriptions, see R. S. Conway, *The Italic Dialects*, p. 449, where the place-names and personal names of the district will also be found; see further, Livy, *Epit.* xv.; B. V. Head, *Historia numorum*, p. 19. (R. S. C.)

It was in Picenum, at Asculum, that the Social War broke out in 90 B.C. At the end of the war the district became connected with Pompeius Strabo, and his son Pompey the Great threw into the scale on the side of Sulla, in 83 B.C., all the influence he possessed there, and hoped to make it a base against Caesar's legions in 49 B.C. Under Augustus it formed the fifth region of Italy, and included twenty-three independent communities, of which five, Ancona, Firmum, Asculum, Hadria and Interamnia, were *coloniae*. It was reached from Rome by the Via Salaria, and its branch the Via Caecilia. It was also on a branch leading from the Via Flaminia at Nuceria Camellaria to Septempeda. There were also communications from north to south; a road led from Asculum to Urbs Salvia and Ancona, another from Asculum and Firmum and the coast, another from Urbs Salvia to Potentia, while finally along the whole line of the coast there ran a prolongation of the Via Flaminia, the name of which is not known to us.

At the end of the 2nd century A.D. the north-eastern portion of Umbria was divided from the rest and acquired the name Flaminia, from the high road. For the time it remained united with Umbria for administrative purposes, but passed to Picenum at latest in the time of Constantine, and acquired the name of *Flaminia et Picenum Annonarium*, the main portion of Picenum being distinguished as *Suburbicarium*. In an inscription of A.D. 399 Ravenna is actually spoken of as the chief town of Picenum. When the exarchate of Ravenna was founded the part of Picenum Annonarium near the sea became the Pentapolis Maritima, which included the five cities of Ariminum, Pisaurum, Fanum Fortunae, Sena Gallica and Ancona. The exarchate was seized by Luitprand in 727, and Ravenna itself was taken by Aistulf in 752. In the next year, however, the Emperor Pippin took it from him and handed it over to the pope, a grant confirmed by his son Charlemagne. (T. As.)

PICHEGRU, CHARLES (1761–1804), French general, was born at Arbois, or, according to Charles Nodier, at Les Planches, near Lons-le-Saulnier, on the 16th of February 1761. His father was a labourer, but the friars of Arbois gave the boy a good education, and one of his masters, the Père Partault, took him to the military school of Brienne. In 1783 he entered the first regiment of artillery, where he rapidly rose to the rank of adjutant-sub-lieutenant. When the Revolution began he became leader of the Jacobin party in Besançon, and when a regiment of volunteers of the department of the Gard marched through the city he was elected lieutenant-colonel. The fine condition of his regiment was soon remarked in the army of the Rhine, and his organizing ability was made use of by an appointment on the staff, and finally by his promotion to the rank of general of brigade. In 1793 Carnot and Saint Just were sent to find *roturier* generals who could be successful; Carnot discovered Jourdan, and Saint Just discovered Hoche and Pichegru. In co-operation with Hoche and the army of the Moselle, Pichegru, now general of division and in command of the army of the Rhine, had to reconquer Alsace and to reorganize the disheartened troops of the republic. They succeeded; Pichegru made use of the *élan* of his soldiers to win innumerable small engagements, and with Hoche forced the lines of Haguenau and relieved Landau. In December 1793 Hoche was arrested, it is said owing in part to his colleague's machinations, and Pichegru became commander-in-chief of the army of the Rhine-and-Moselle, whence he was summoned to succeed Jourdan in the army of the North in February 1794. It was now that he fought his three great campaigns of one year. The English and Austrians held a strong position along the Sambre to the sea. After vainly attempting to break the Austrian centre, Pichegru suddenly turned their left, and defeated Clerfayt at Cassel, Menin and Courtrai, while Moreau, his second in command, defeated Coburg at Tourcoing in May 1794; then after a pause, during which Pichegru feigned to besiege Ypres, he again dashed at Clerfayt and defeated him at Rousselaer and Hooglede, while Jourdan came up with the new army of the Sambre-and-Meuse, and utterly routed the Austrians at Fleurus on the 27th of June 1794. Pichegru began his second campaign by crossing the Meuse on the 18th of October, and after taking Nijmwegen drove the Austrians beyond the Rhine. Then, instead of going into winter quarters, he prepared his army for a winter

campaign. On the 28th of December he crossed the Meuse on the ice, and stormed the island of Bommel, then crossed the Waal in the same manner, and, driving the English before him, entered Utrecht on the 19th of January, and Amsterdam on the 20th of January, and soon occupied the whole of Holland. This grand feat of arms was marked by many points of interest, such as the capture of the Dutch ships, which were frozen in the Helder, by the French hussars, and the splendid discipline of the ragged battalions in Amsterdam, who, with the richest city of the continent to sack, yet behaved with a self-restraint which few revolutionary and Napoleonic armies attained. The former friend of Saint Just now offered his services to the Thermidorians, and after receiving from the Convention the title of "Sauveur de la Patrie," subdued the *sans-culottes* of Paris, when they rose in insurrection against the Convention on 12 Germinal (April 1). Pichegru then took command of the armies of the North, the Sambre-and-Meuse, and the Rhine, and crossing the Rhine in force took Mannheim in May 1795. When his fame was at its height he allowed his colleague Jourdan to be beaten, betrayed all his plans to the enemy, and took part in organizing a conspiracy for the return of Louis XVIII., in which he was to play, for his own aggrandizement, the part that Monk played from higher motives in the English revolution. His intrigues were suspected, and when he offered his resignation to the Directory in October 1795 it was to his surprise promptly accepted. He retired in disgrace, but hoped to serve the royalist cause by securing his election to the Council of Five Hundred in May 1797. He was there the royalist leader, and planned a *coup d'état*, but on the 18th Fructidor he was arrested, and with fourteen others deported to Cayenne in 1797. Escaping, he reached London in 1798, and served on General Korsakov's staff in the campaign of 1799. He went to Paris in August 1803 with Georges Cadoudal to head a royalist rising against Napoleon; but, betrayed by a friend, he was arrested on the 28th of February 1804, and on the 15th of April was found strangled in prison. It has often been asserted that he was murdered by the orders of Napoleon, but there is no foundation for the story.

Pichegru's campaigns of 1794 are marked by traits of an audacious genius which would not have disgraced Napoleon. His tremendous physical strength, the personal ascendancy he gained by this and by his powers of command made him a peculiarly formidable opponent, and thus enabled him to maintain a discipline which guaranteed the punctual execution of his orders. He had also, strangely enough, the power of captivating honest men like Moreau. He flattered in turn Saint Just and the Terrorists, the Thermidorians and the Directors, and played always for his own hand—a strange egoist who rose to fame as the leader of an idealist and sentimental crusade.

There is no really good life of Pichegru; perhaps the best is J. M. Gassier's *Vie du général Pichegru* (Paris, 1815). For his treason, trial and death, consult Montgaillard's *Mémoires concernant la trahison de Pichegru* (1804); Fauche-Borel's *Mémoires*; Savary, *Mémoires sur la mort de Pichegru* (Paris, 1825); and G. Pierret, *Pichegru, son procès et sa mort* (1826).

PICHLER, KAROLINE (1769–1843), Austrian novelist, was born at Vienna on the 7th of September 1769, the daughter of Hofrat Franz von Greiner, and married, in 1796, Andreas Pichler, a government official. For many years her salon was the centre of the literary life in the Austrian capital, where she died on the 9th of July 1843. Her early works, *Olivier*, first published anonymously (1802), *Idyllen* (1803) and *Ruth* (1805), though displaying considerable talent, were immature. She made her mark in historical romance, and the first of her novels of this class, *Agathocles* (1808), an answer to Gibbon's attack on that hero in the *Decline and Fall of the Roman Empire*, attained great popularity. Among her other novels may be mentioned *Die Belagerung Wiens* (1824); *Die Schweden in Prag* (1827); *Die Wiedereroberung Ofens* (1829) and *Henriette von England* (1832). Her last work was *Zeitbilder* (1840).

The edition of Karoline Pichler's *Sämtliche Werke* (1820–1845) comprises no less than 60 volumes. Her *Denkwürdigkeiten aus meinem Leben* (4 vols.) was published posthumously in 1844. A selection of her narratives, *Ausgewählte Erzählungen*, appeared in 4 vols. in 1894.

PICKENS, ANDREW (1739–1817), American soldier in the War of Independence, was born in Paxton, Bucks county, Pennsylvania, on the 19th of September 1739. His family settled at the Waxhaws (in what is now Lancaster county), South Carolina, in 1752. He fought against the Cherokees in 1761 as a lieutenant. In the War of Independence he rose to brigadier-general (after Cowpens) in the South Carolina militia. He was a captain among the American troops which surrendered at Ninety Six in November 1775. On the 14th of February 1779, with 300–400 men, he surprised and defeated about 700 Loyalists under Colonel Boyd on Kettle Creek, Wilkes county, Georgia; on the 20th of June he fought at Stono Ferry; and later in the same year at Tomassee defeated the Cherokees, who were allied with the British. Upon the surrender of Charleston (May 1780) he became a prisoner on parole, which he observed rigidly until, contrary to the promises made to him, Major James Dunlap plundered his plantation; he then returned to active service. His command (about 150 men) joined General Daniel Morgan immediately before the battle of Cowpens, in which Pickens commanded an advance guard (270–350 men from Georgia and North Carolina) and twice rallied the broken American militia; for his services Congress gave him a sword. With Colonel Henry Lee he harassed Lieut.-Colonel Banastre Tarleton, who was attempting to gather a Loyalist force just before the battle of Guilford Court House; and with Lee and others he captured Augusta (June 5, 1781) after a siege. At Eutaw Springs (Sept. 8, 1781) he commanded the left wing and was wounded. In 1782 he defeated the Cherokees again and forced them to surrender all lands south of the Savannah and east of the Chattahoochee. After the war he was a member of the South Carolina House of Representatives for a number of years, of the state Constitutional Convention in 1790, and of the National House of Representatives in 1793–1795. He died in Pendleton district, South Carolina, on the 17th of August 1817. He had married in 1765 Rebecca Calhoun, an aunt of John C. Calhoun. Their son, ANDREW PICKENS (1779–1838), served as a lieutenant-colonel in the war of 1812, and was governor of South Carolina in 1816–1818.

PICKENS, FRANCIS WILKINSON (1805–1869), American politician, was born in Togadoo, St Paul's parish, South Carolina, on the 7th of April 1805, son of Andrew Pickens (1779–1838) and grandson of General Andrew Pickens (1739–1817). He was educated at Franklin College, Athens, Georgia, and at South Carolina College, Columbia, and was admitted to the bar in 1829. In 1832 he was elected to the state House of Representatives, where, as chairman of a sub-committee, he submitted a report denying the right of Congress to exercise any control over the states. He was a Democratic member of the National House of Representatives in 1834–1843, served in the South Carolina Senate in 1844–1845, was a delegate to the Nashville Southern Convention (see NASHVILLE, TENNESSEE) in 1850, was United States minister to Russia in 1858–1860, and in 1860–1862 was governor of South Carolina. He strongly advocated the secession of the southern states; signed the South Carolina ordinance of secession; protested against Major Robert Anderson's removal from Fort Moultrie to Fort Sumter; sanctioned the firing upon the "Star of the West" (Jan. 9, 1861), which was bringing supplies to Anderson, and the bombardment of Fort Sumter; and was a zealous supporter of the Confederate cause. At the close of his term he retired to his home at Edgefield, South Carolina, where he died on the 25th of January 1869.

PICKERING, EDWARD CHARLES (1846–   ), American physicist and astronomer, was born in Boston on the 19th of July 1846. He graduated in 1865 at the Lawrence Scientific School of Harvard, where for the next two years he was a teacher of mathematics. Subsequently he became professor of physics at the Massachusetts Institute of Technology, and in 1876 he was appointed professor of astronomy and director of the Harvard College observatory. In 1877 he decided to

devote one of the telescopes of the observatory to stellar photometry, and after an exhaustive trial of various forms of photometers, he devised the meridian photometer (see PHOTOMETRY, STELLAR), which seemed to be free from most of the sources of error. With the first instrument of this kind, having objectives of 1·5 inch aperture, he measured the brightness of 4260 stars, including all stars down to the 6th magnitude between the North Pole and −30° declination. With the object of reaching fainter stars, Professor Pickering constructed another instrument of larger dimensions, and with this more than a million observations have been made. The first important work undertaken with it was a revision of the magnitudes given in the Bonn *Durchmusterung*. On the completion of this, Professor Pickering decided to undertake the survey of the southern hemisphere. An expedition, under the direction of Professor S. I. Bailey, was accordingly despatched (1889), and the meridian photometer erected successively in three different positions on the slopes of the Andes. The third of these was Arequipa, at which a permanent branch of the Harvard Observatory is now located. The magnitudes of nearly 8000 southern stars were determined, including 1428 stars of the 6th magnitude and brighter. The instrument was then returned to Cambridge (U.S.A.), where the survey extended so as to include all stars of magnitude 7·5 down to −40° declination, after which it was once more sent back to Arequipa. In 1886 the widow of Henry Draper, one of the pioneers of stellar spectroscopy, made a liberal provision for carrying on spectroscopic investigations at Harvard College in memory of her husband. With Professor Pickering's usual comprehensiveness, the inquiry was so arranged as to cover the whole sky; and with four telescopes—two at Cambridge for the northern hemisphere, and two at Arequipa in Peru for the southern—to which a fine 24-in. photographic telescope was afterwards added, no fewer than 75,000 photographs had been obtained up to the beginning of 1901. These investigations have yielded many important discoveries, not only of new stars, and of large numbers of variable stars, but also of a wholly new class of double stars whose binary character is only revealed by peculiarities in their spectra. The important conclusion has been already derived that the majority of the stars in the Milky Way belong to one special type.

PICKERING, TIMOTHY (1745–1829), American politician, was born at Salem, Massachusetts, on the 17th of July 1745. He graduated from Harvard College in 1763 and was admitted to the bar in 1768. In the pre-revolutionary controversies he identified himself with the American Whigs; in 1773 he prepared for Salem a paper entitled *State of the Rights of the Colonists*; in 1775 he drafted a memorial protesting against the Boston Port Bill; and in 1776 he was a representative from Salem in the general court of Massachusetts. In 1766 he had been commissioned lieutenant and in 1769 captain in the Essex county militia; early in 1775 he published *An Easy Plan of Discipline for a Militia*, adopted in May 1776 by the general court for use by the militia of Massachusetts, and he was elected colonel of his regiment. In the same year he became judge of the court of common pleas for Essex county, and sole judge of the maritime court for the counties of Suffolk, Essex and Middlesex. In the winter of 1776–1777 he led an Essex regiment of volunteers to New York, and he subsequently served as adjutant-general (June 1777–Jan. 1778) and later as quartermaster-general (1780–1785); he was also a member of the board of war from the 7th of November 1777 until its abolition. With the aid of some officers he drew up, in April 1783, a plan for the settlement of the north-west territory, which provided for the exclusion of slavery. In 1785 he became a commission merchant in Philadelphia; but in October 1786, soon after the legislature of Pennsylvania had passed a bill for erecting Wyoming district into the county of Luzerne, he was appointed prothonotary and a judge of the court of common pleas and clerk of the court of sessions and orphans, court for the new county, and was commissioned to organize the county. He offered to purchase for himself the Connecticut title to a farm, and in the following year he was appointed a member of a commission to settle claims according to the terms of an act, of which he was the author, confirming the Connecticut titles (see WYOMING VALLEY and WILKES-BARRÉ). Pickering was a member of the Pennsylvania convention of 1787 (which ratified the federal constitution) and of the Pennsylvania constitutional convention of 1789–1790. In November 1790 he negotiated a peace with the Seneca Indians, and he concluded treaties with the Six Nations in July 1791, in March 1792 and in November 1794. Under Washington he was postmaster-general (1791–1795), secretary of war (1795), and after December 1795 secretary of state, to which position he was reappointed (1797) by Adams. In 1783, while he was quartermaster-general, he had presented a plan for a military academy at West Point, and now, as secretary of war, he supervised the West Point military post with a view to its conversion into a military academy. As head of the state department he soon came into conflict with Adams. His hatred of France made it impossible for him to sympathize with the president's efforts to settle the differences with that country on a peaceable basis. He used all his influence to hamper the president and to advance the political interests of Alexander Hamilton, until he was dismissed, after refusing to resign, in May 1800. Returning to Massachusetts, he served as chief justice of the court of common pleas of Essex county in 1802–1803. He was a United States Senator in 1803–1811 and a member of the Federal House of Representatives in 1813–1817. As an ultra Federalist—he was a prominent member of the group known as the Essex Junto—he strongly opposed the purchase of Louisiana and the war of 1812. He died at Salem, Massachusetts, on the 29th of January 1829.

The standard biography is that by his son, Octavius Pickering (1791–1868) and C. W. Upham, *The Life of Timothy Pickering* (4 vols., Boston 1867–1873). In the library of the Massachusetts Historical Society at Boston, there are sixty-two manuscript volumes of the Pickering papers, an index to which was published in the *Collections* of the society, 6th series, vol. viii. (Boston, 1896).

His son, JOHN PICKERING (1777–1846), graduated at Harvard in 1796, studied law and was private secretary to William Smith, United States minister to Portugal, in 1797–1799, and to Rufus King, minister to Great Britain, in 1799–1801. He practised law in Salem and (after 1827) in Boston, where he was city solicitor in 1827–1846, and wrote much on law and especially on the languages of the North-American Indians. He was a founder of the American Oriental Society and published an excellent *Comprehensive Dictionary of the Greek Language* (1826).

See Mary O. Pickering (his daughter), *Life of John Pickering* (Boston, 1887).

Timothy Pickering's grandson, CHARLES PICKERING (1805–1878), graduated at Harvard College in 1823 and at the Harvard Medical School in 1826, practised medicine in Philadelphia, was naturalist to the Wilkes exploring expedition of 1838–1842, and in 1843–1845 travelled in East Africa and India. He wrote *The Races of Man and their Geographical Distribution* (1848), *Geographical Distribution of Animals and Man* (1854), *Geographical Distribution of Plants* (1861) and *Chronological History of Plants* (1879).

PICKERING, a market town in the Whitby parliamentary division of the North Riding of Yorkshire, England, 32 m. N.E. by N. from York by the North Eastern railway, the junction of several branch lines. Pop. of urban district (1901), 3491. The church of St Peter is Norman and transitional Norman, with later additions including a Decorated spire. It contains a remarkable series of mural paintings of the 15th century. The castle, on a hill to the north, is a picturesque ruin, the fragmentary keep and several towers remaining. The work is in part Norman, but the principal portions are of the 14th century. One of the towers is connected in name and story with Fair Rosamond. The castle was held by Earl Morcar shortly before the Conquest; it then came into the hands of the Crown, and subsequently passed to the duchy of Lancaster. It was the prison of Richard II. before his confinement at Pontefract. During the Civil Wars of the 17th century the castle was held by the Royalists, and suffered greatly in siege. The district

surrounding Pickering is agricultural, and the town is a centre of the trade. Agricultural implements are manufactured, and limestone and freestone are quarried in the vicinity.

PICKET, PIQUET or PICQUET (Fr. *piquet*, a pointed stake or peg, from *piquer*, to point or pierce), a military term, signifying an outpost or guard, supposed to have originated in the French army about 1690, from the circumstance that an infantry company on outpost duty dispersed its musketeers to watch, the small group of pikemen called *piquet* remaining in reserve. Thus at the present day the word "picquet" is, in Great Britain at any rate, restricted to an infantry post on the outpost line, from which the sentries or "groups" of watchers are sent out. In the United States a "picket" is synonymous with a sentry, and the "picket-line" is the extreme advanced line of observation of an army. In the French army picquets are called "grand' gardes," and the phrase "grand guard" is often met with in English military works of the 17th and 18th centuries. A body of soldiers held in readiness for military or police duties within the limits of a camp or barracks is also called a picquet or "inlying picquet." These special uses of the word in English are apparently quite modern (after about 1750). "Picket" in its ordinary meaning of a peg or stake, has always been in common military use, being applied variously to the picketing pegs in horse-lines, to long pointed stakes employed in palisades or stockades, to straight thin rods used for marking out the line of fire for guns, &c. Of the various spellings "picquet" is officially adopted in Great Britain and "picket" in the United States, but the latter is now invariably used when a peg or stake is meant.

Two obsolete meanings of the word should also be mentioned. The "picket" was a form of military punishment in vogue in the 16th and 17th centuries, which consisted in the offender being forced to stand on the narrow flat top of a peg for a period of time. The punishment died out in the 18th century and was so far unfamiliar by 1800 that Sir Thomas Picton, who ordered a mulatto woman to be so punished, was accused by public opinion in England of inflicting a torture akin to impalement. It was thought, in fact, that the prisoner was forced to stand on the head of a pointed stake, and this error is repeated in the *New English Dictionary*. In the middle of the 19th century, when elongated rifle bullets were a novelty, they were often, and especially in America, called pickets. The ordinary military use of the word gives rise to compound forms such as "picket boat" or "picket launch," large steam launch or pinnace fitted with guns and torpedoes, and employed for watching the waters of harbours, &c. For picketing in strikes, &c., see below.

PICKETING, a term used to describe a practice resorted to by workmen engaged in trade disputes, of placing one or more men near the works of the employer with whom the dispute is pending, with the object of drawing off his hands or acquiring information useful for the purposes of the dispute. In England, under the Conspiracy and Protection of Property Act 1875, it is an offence wrongfully and without legal authority to watch or beset the house or place where another resides or works, or carries on business or happens to be, or the approach to such house or place, if the object of the watching, &c., is to compel the person watched, &c., to abstain from doing or to do an act which he is legally entitled to do or to abstain from doing (§ 7). The definition of the offence was qualified by a proviso excluding from punishment those who attend at or near a house or place merely to obtain or communicate information, in other words what is termed peaceful picketing, without intimidation, molestation or direct efforts to influence the course of a trade dispute. This enactment led to a great deal of litigation between trade unions and employers; and trade unions were in some instances restrained by injunction from picketing the works of employers. The decisions of the courts upon this subject met with severe criticism from the leaders of trade unions, and by the Trades Disputes Act 1906 the proviso above quoted was repealed, and it was declared lawful for one or more persons acting for themselves or for a trade union or for an individual employer to attend at or near a house, &c., "if the attendance is merely for the purpose of peacefully obtaining or communicating information or of peacefully persuading any person to work or abstain from working." The exact effect of this change in the law has not yet been determined by the courts, but during the Belfast carters' strike of 1907 serious riots ensued upon the efforts of the authorities to counteract the interference with lawful business caused by free use of picketing. The change in the law is supplemented by provisions forbidding actions against trade unions in respect of any tortious acts alleged to have been committed by or on behalf of the union.

PICKLE. In the wider sense the term "pickle" is applied to any saline or acid preservative solution; in the narrower to vegetables preserved in vinegar. The word appears to be an adaptation of Dutch *pekel*, brine, pickle; cf. Ger. Pökel. The ultimate origin is unknown; connexions with a supposed inventor's name, such as *Beukeler* or *Böckel* are mere inventions. A solution of copper or zinc sulphate is used as a "pickle" for railway-sleepers or other wood, a brine containing salt and saltpetre as a preservative for meat, lime-water as "pickle" for eggs. Domestic pickles are made from small cucumbers, onions, cauliflowers, cabbages, mangoes and unripe walnuts, by either steeping or boiling them in salt-brine and vinegar. On account of the large proportion of water natural to these vegetables, only the strongest vinegar, containing from 5 to 6 % of acetic acid, can be used. For the better kinds vinegar made from malted or unmalted barley is as a rule employed, for cheaper varieties simply dilute acetic acid obtained from acetate of lime. Sauces such as Worcestershire sauce, or Yorkshire relish, consist of fluid pickles, that is of salted and variously spiced vinegar solutions or emulsions containing tissue of vegetables (tomatoes, mushrooms, &c.), or of fish (sardines or anchovies).

PICKNELL, WILLIAM LAMB (1854–1897), American landscape-painter, was born at Hinesburg, Vermont, on the 23rd of October 1854. He was a pupil of George Inness in Rome for two years, and of J. L. Gérôme in the École des Beaux Arts, Paris. With Robert Wylie he worked for several years in Brittany, at Pont Aven and Concarneau, where he painted his "Route de Concarneau" (Corcoran Art Gallery, Washington, D.C.). His "Morning on the Loing" received a gold medal at the Paris Salon of 1895. In 1880 he became a member of the Society of American Artists, and in 1891 an associate of the National Academy of Design. He died at Marblehead, Massachusetts, on the 8th of August 1897.

PICNIC, a form of entertainment in which the guests are invited to join an excursion to some place where a meal can be taken in the open air. During the first half of the 19th century the essential of a picnic was that the guests should each bring with them a contribution of provisions. At the beginning of the 19th century a society was formed in London called the "Picnic Society," the members of which supped at the Pantheon in Oxford Street, and drew lots as to what part of the meal each should supply (see L. Melville, *The Beaux of the Regency*, 1908, i. 222). The French form *pique-nique* is said to be of recent introduction in 1692 (Ménage, *Dict. etym.*). It is doubtful whether picnic is merely a rhyming word, or can be referred to *pique*, pick, and *nique*, small coin.

PICO, an island in the Atlantic Ocean, belonging to Portugal, and forming part of the Azores archipelago. Pop. (1900), 24,028; area 175 sq. m. Pico is a conical mountain, rising to the height of 7612 ft. The soil consists entirely of pulverized lava. The so-called Fayal wine, though named after an adjacent island, was formerly produced here, and largely exported to Europe. But in 1852 the vines were attacked by the *Oidium* fungus and completely destroyed, while the orange-trees suffered almost as much from the *Coccus hesperidum*. The people were consequently forced to emigrate in great numbers, till the planting of fig-trees and apricots alleviated the evil. Pico also produces a species of wood resembling mahogany, and equal in quality to it. Its chief town is Lagens do Pico; pop. 2975.

PICO DELLA MIRANDOLA, GIOVANNI, COUNT (1463–1494), Italian philosopher and writer, the youngest son of Giovanni

Francesco Pico, prince of Mirandola, a small territory about 30 Italian miles west of Ferrara, afterwards absorbed in the duchy of Modena, was born on the 24th of February 1463. The family was illustrious and wealthy, and claimed descent from Constantine. In his fourteenth year Pico went to Bologna, where he studied for two years, and was much occupied with the Decretals. The traditional studies of the place, however, disgusted him; and he spent seven years wandering through all the schools of Italy and France and collecting a precious library. Besides Greek and Latin he knew Hebrew, Chaldee and Arabic; and his Hebrew teachers (Eliah del Medigo, Leo Abarbanel and Jochanan Aleman—see L. Geiger, *Johann Reuchlin*, 1871, p. 167) introduced him to the Kabbalah, which had great fascinations for one who loved all mystic and theosophic speculation. His learned wanderings ended (1486) at Rome, where he set forth for public disputation a list of nine hundred questions and conclusions in all branches of philosophy and theology. He remained a year in Rome, but the disputation he proposed was never held. The pope prohibited the little book in which they were contained, and Pico had to defend the impugned theses (*De omni re scibili*) in an elaborate *Apologia*. His personal orthodoxy was, however, subsequently vindicated by a brief of Alexander VI., dated 18th June 1493. The suspected theses included such points as the following: that Christ descended *ad inferos* not in His real presence but *quoad effectum*; that no image or cross should receive *latreia* even in the sense allowed by Thomas; that it is more reasonable to regard Origen as saved than as damned; that it is not in a man's free will to believe or disbelieve an article of faith as he pleases. But perhaps the most startling thesis was that no science gives surer conviction of the divinity of Christ than "magia" (*i.e.* the knowledge of the secrets of the heavenly bodies) and Kabbalah. Pico was the first to seek in the Kabbalah a proof of the Christian mysteries and it was by him that Reuchlin was led into the same delusive path.

Pico had been up to this time a gay Italian nobleman; he was tall, handsome, fair-complexioned, with keen grey eyes and yellow hair, and a great favourite with women. But his troubles led him to more serious thoughts; and he published, in his 28th year, the *Heptaplus*, a mystical exposition of the creation. Next he planned a great seven-fold work against the enemies of the Church, of which only the section directed against astrology was completed. After leaving Rome he again lived a wandering life, often visiting Florence, to which he was drawn by his friends Politian and Marsilius Ficinus, and where also he came under the influence of Savonarola. It was at Florence that he died on the 17th of November 1494. Three years before his death he parted with his share of the ancestral principality, and designed, when certain literary plans were completed, to give away all he had and wander barefoot through the world preaching Christ. But these plans were cut short by a fever which carried him off just at the time when Charles VIII. was at Florence.

Pico's works cannot now be read with much interest, but the man himself is still interesting, partly from his influence on Reuchlin and partly from the spectacle of a truly devout mind in the brilliant circle of half-pagan scholars of the Florentine renaissance.

His works were published at Bologna in 1496 by his nephew, Giov. Fran. Pico, with a biography, which was translated by Sir Thomas More as *Life of John Picus, Earl of Mirandola*, in 1510. See the essay in Walter Pater's *Renaissance* (1878); and the study by J. Rigg, prefixed to the reprint of More's *Life* in the "Tudor Library" (London, 1890).

PICRIC ACID, or TRINITROPHENOL, $C_6H_2 \cdot OH \cdot (NO_2)_3$ [1·2·4·6], an explosive and dyestuff formed by the action of concentrated nitric acid on indigo, aniline, resins, silk, wool, leather, &c. It is the final product of the direct nitration of phenol, and is usually prepared by the nitration of the mixture of phenol sulphonic acids obtained by heating phenol with concentrated sulphuric acid (E. Eisenmann and A. Arche, Eng. pat., 4539; 1889). It may also be obtained by oxidizing the symmetrical trinitrobenzene with potassium ferricyanide in alkaline solution (P. Hepp, *Ann.* 1882, 215, p. 352). It crystallizes from water in yellow plates melting at 122·5° C., which sublime on careful heating, but explode when rapidly heated. It is poisonous and possesses a bitter taste, hence its name from the Greek πικρός, bitter. It has a strongly acid reaction, being almost comparable with the carboxylic acids. By the action of bleaching powder it is converted into chlorpicrin, $CCl_3 \cdot NO_2$. Phosphorus pentachloride converts it into picryl chloride, $C_6H_2Cl(NO_2)_3$, which is a true acid chloride, being decomposed by water with the regeneration of picric acid and the formation of hydrochloric acid; with ammonia it yields *picramide*, $C_6H_2NH_2(NO_2)_3$. Silver picrate and methyl iodide yield the methyl ester, which gives with ammonia picramide. Picric acid forms many well-defined salts, of a yellow or red-brown colour. It also yields crystalline compounds with many aromatic hydrocarbons and bases. It imparts a yellow colour to wool and silk. The chief application of picric acid and its salts is in the manufacture of explosives. When ignited, picric acid burns quietly with a smoky flame, and it is very difficult to detonate by percussion; its salts, however, are more readily detonated. The more important picric powders are *melinite*, believed to be a mixture of fused picric acid and gun-cotton; *lyddite*, the British service explosive, and *shimose*, the Japanese powder, both supposed to be identical with the original melinite; *Brugère's powder*, a mixture of 54 parts of ammonium picrate and 45 parts of saltpetre; *Designolle's powder*, composed of potassium picrate, saltpetre and charcoal; and *emmensite*, invented by Stephen Emmens, of the United States.

It may be detected by the addition of an aqueous solution of potassium cyanide, with which it gives a violet-red coloration, due to the formation of isopurpuric acid. R. Anschutz (*Ber.*, 1884, 17, p. 439) estimates picric acid by precipitation with acridine.

PICRITE (from Gr. πικρός, bitter, because these rocks are rich in magnesia, a base which forms bitter salts), a rock belonging to the ultrabasic group, and consisting mainly of olivine and augite often with hornblende and biotite and a greater or less amount of plagioclase felspar. The picrites are of "hypabyssal" origin and in their natural occurrence are connected with dolerites (diabases and teschenites). The distinction between them and the peridotites, which have an essentially similar composition, is not easy to define, but the peridotites accompany the true plutonic rocks, such as gabbro, norite and pyroxenite, are often very coarsely crystalline, and form large bosses and laccolites, while the picrites usually are found in sills or intrusive sheets.

In hand specimens the picrites are dark green to black; the absence or scarcity of lath-shaped plagioclase felspars distinguishes them from diabases and they rarely have the lustre-mottling which is a characteristic of the peridotites. Since they contain much olivine they readily decompose, passing into deep green and brown incoherent masses in which are embedded rounded lumps of harder consistency. They have a high specific gravity (about 3·0) and may be distinctly magnetic, because they are rich in iron ores. Porphyritic structure is rare though occurring sometimes in the rocks known as picrite-porphyrites; the phenocrysts are olivine and augite. There is seldom any fine-grained or glassy groundmass, and the typical micro-structure is holocrystalline, moderately fine grained and somewhat poikilitic. Olivine is abundant in rounded pale green crystals. It may form one half of the rock but rarely more than this. The augite is generally brown or reddish-brown, sometimes violet, and tends to enclose the olivine, yielding poecilitic aggregates. Brown hornblende often occurs as marginal growths around the pyroxene, and may be so abundant as to replace augite to a large extent; rocks of this class are known as hornblende-picrites. Bright green or pale-green hornblende are less frequently present, and in many cases are really of secondary origin. Deep brown biotite is a frequent accessory mineral and both biotite and hornblende sometimes enclose olivine. A small amount of basic plagioclase occurs in many picrites; apatite, iron oxides, chromite and spinels are minor ingredients seldom altogether absent.

The minerals of picrites are very frequently decomposed. Serpentine partly or wholly replaces olivine, forming radiate fibrous masses which are green, yellow or red in microscopic sections. Sometimes hornblende (pilite), talc, chlorite and mica appear as secondary products after olivine. The augite passes into chlorite or into green fibrous or platy amphibole. Hornblende and biotite are often fresh when the other components are much altered. The felspar is rarely in good preservation, but yields epidote, prehnite, sericite, kaolin; calcite and analcite are abundant in some weathered picrites.

Rocks of this type are well represented in Great Britain. In the central valley of Scotland several masses of picrite have been discovered, always in close association with olivine-diabase and teschenite. One of these forms the island of Incheolm in the Firth of Forth, another lies near Bathgate (in Linlithgowshire), and there are others at Aberdour (Fife), Ardrossan and Barnton (Midlothian). They belong to the great series of Carboniferous eruptive rocks of the Scottish midland valley. These picrites are not known to be represented in England, but, on the other hand, there are Devonian picrites in Devon and Cornwall as basic members of the diabase and proterobase series of these counties. Some of them contain much augite like the picrite (often called palaeopicrite as being of palaeozoic age) at Menheniot Station in Cornwall and the picrite of Highweek near Newton Abbot in Devonshire. Others are hornblende-picrites like that of Cartuther, near St Germans, Cornwall. Hornblende-picrite occurs also in the island of Sark and several beautiful examples have been described from Anglesey and from Penarfynnydd in North Wales and from Wicklow in Ireland. Picrites occur in several parts of Germany, notably in the Devonian rocks of the Fichtelgebirge and Nassau, where they accompany diabases and proterobases like those of Cornwall and Devonshire. In Silesia and Moravia picrites are found with teschenites like those of Central Scotland. In some of the continental picrites enstatite is present but is rare. In North America picrites occur among the igneous rocks on the Hudson River and in Alabama and Montana. (J. S. F.)

PICROTOXIN, a neutral principle obtained from the *Cocculus indicus*, which is the fruit of the *Anamirta paniculata*. It is used in medicine externally as an antiparasitic. Internally it has been successfully used to check the night-sweats of phthisis. In large doses it is a powerful poison, causing unconsciousness, delirium, convulsions, gastro-enteritis and stimulation of the respiratory centre followed by paralysis, from which death sometimes results. Formerly low-class publicans sometimes added *Cocculus indicus* berries to beer to increase the intoxicating effects. Its chemical formula is $C_{15}H_{16}O_6.H_2O$.

PICTET DE LA RIVE, FRANÇOIS JULES (1809–1872), Swiss zoologist and palaeontologist, was born in Geneva on the 27th of September 1809. He graduated B. ès Sc. at Geneva in 1829, and pursued his studies for a short time at Paris, where, under the influence of Cuvier, de Blainville and others, he worked at natural history and comparative anatomy. On his return to Geneva in 1830 he assisted A. P. de Candolle by giving demonstrations in comparative anatomy. Five years later, when De Candolle retired, Pictet was appointed professor of zoology and comparative anatomy. In 1846 his duties were restricted to certain branches of zoology, including geology and palaeontology, and these he continued to teach until 1859, when he retired to devote his energies to the museum of natural history and to special palaeontological work. He was rector of the academy from 1847 to 1850, and again from 1866 to 1868. He was for many years a member of the Representative Council of Geneva, and in 1862 President of the Constituent Assembly. His earlier published work related chiefly to entomology, and included *Recherches pour servir à l'histoire et à l'anatomie des Phryganides* (1834) and two parts of *Histoire naturelle, générale et particulière des insectes Neuroptères* (1842–1845). Feeling the want of a handbook, he prepared his *Traité élémentaire de paléontologie* (4 vols. 1844–1846). In the first edition Pictet, while adopting the hypothesis of successive creations of species, admitted that some may have originated through the modification of pre-existing forms. In his second edition (1853–1857) he enters further into the probable transformation of some species, and discusses the independence of certain faunas, which did not appear to have originated from the types which locally preceded them. He now directed his attention to the fossils of his native country, more especially to those of the Cretaceous and Jurassic strata, and in 1854 he commenced the publication of his great work, *Matériaux pour la paléontologie suisse*, a series of quarto memoirs, of which six were published (1854–1873). In this work Pictet was aided by E. Renevier, G. Campiche, P. de Loriol and others. Pictet also brought out *Mélanges paléontologiques* (1863–1868). He died at Geneva on the 15th of March 1872.

Obituary by W. S. Dallas, *Quart. Journ. Geol. Soc.* (1873), vol. xxix.

PICTON, SIR THOMAS (1758–1815), British general, was the younger son of Thomas Picton, of Poyston, Pembrokeshire, where he was born in August 1758. In 1771 he obtained an ensign's commission in the 12th regiment of foot, but he did not join until two years afterwards. The regiment was then stationed at Gibraltar, where he remained until he was made captain in the 75th in January 1778, when he returned to England. The regiment was disbanded five years later. On the occasion of its disbandment Picton quelled a mutiny amongst the men by his prompt personal action and courage, and was promised a majority in reward for his conduct. This, however, he did not receive, and after living in retirement on his father's estate for nearly twelve years, he went out to the West Indies in 1794 on the strength of a slight acquaintance with Sir John Vaughan, the commander-in-chief, who made him his aide-de-camp and gave him a captaincy in the 17th foot. Shortly afterwards he was promoted major. Under Sir Ralph Abercromby, who succeeded Vaughan in 1795, he took part in the capture of St Lucia (for which he was promoted lieutenant-colonel) and in that of St Vincent. After the reduction of Trinidad Abercromby made him governor of the island. He administered the island with such success that the inhabitants petitioned against the retrocession of the island to Spain, and their protest, with Picton's and Abercromby's representations, ensured the retention of Trinidad as a British possession. In October 1801 he was gazetted brigadier-general. But by this time the rigour of his government, as reported by his enemies, had led to a demand by humanitarians at home for his removal. Colonel William Fullarton (1754–1808) procured the appointment of a commission to govern the island, of which he himself was the senior member, Captain (afterwards Admiral Sir Samuel) Hood the second, and Picton himself the junior. Picton thereupon tendered his resignation, and Hood, as soon as the nature of Fullarton's proceedings became obvious, followed his example (1803). On his way home Picton took part with great credit in military operations in St Lucia and Tobago. Realizing, however, that the attacks upon him were increasing in virulence, he quickly returned to England, and in December 1803 he was arrested by order of the privy council. He was tried in the court of king's bench before Lord Ellenborough in 1806 on a charge of unlawfully applying torture to extort a confession from Luise Calderon, a mulatto woman of loose character who was charged, along with a man, with robbery. The torture consisted in compelling the woman to stand on one leg on a flat-headed peg for one hour. The punishment was ordered under Spanish law (which in default of a fresh code Picton had been appointed to administer in 1801) by the local alcalde, and approved by Picton. On these grounds the court returned a merely technical verdict of guilty, which was superseded in 1808 by a special verdict on retrial. It should be mentioned that the inhabitants of the island, who had already given him a sword of honour, and had petitioned the king not to accept his resignation, subscribed £4000 towards his legal expenses, which sum Picton contributed in return to the relief of the suffering caused by a widespread fire in Port of Spain. He had meanwhile been promoted major-general, and in 1809 he had been governor of Flushing during the Walcheren expedition. In 1810, at Wellington's request, he was appointed to command a division in Spain. For the remaining years of the Peninsular War, Picton was one of Wellington's principal subordinates. The commander-in-chief, it is true, never reposed in him the confidence that he gave to Beresford Hill and Craufurd. But in the resolute, thorough and punctual execution of a well-defined task Picton had no superior in the army. His début,

owing partly to his naturally stern and now embittered temper, and partly to the difficult position in which he was placed, was unfortunate. On the Coa in July 1810 Craufurd's division became involved in an action, and Picton, his nearest neighbour, refused to support him, as Wellington's direct orders were to avoid an engagement. Details of the incident will be found in Oman, *Peninsular War*, vol. iii. Shortly after this, however, at Busaco, Picton found and used his first great opportunity for distinction. Here he had a plain duty, that of repulsing the French attack, and he performed that duty with a skill and resolution which indicated his great powers as a troop-leader. After the winter in the lines of Torres Vedras, he added to his reputation and to that of his division, the 3rd, at Fuentes d'Onor. In September he was given the local rank of lieutenant-general, and in the same month the division won great glory by its rapid and orderly retirement under severe pressure from the French cavalry at El Bodon. In October Picton was appointed to the colonelcy of the 77th regiment. In the first operations of 1812 Picton and Craufurd, side by side for the last time, stormed the two breaches of Ciudad Rodrigo, Craufurd and Picton's second in command, Major-General Mackinnon, being mortally wounded. At Badajoz, a month later, the successful storming of the fortress was due to his daring self-reliance and penetration in converting the secondary attack on the castle, delivered by the 3rd division, into a real one. He was himself wounded in this terrible engagement, but would not leave the ramparts, and the day after, having recently inherited a fortune, he gave every survivor of his command a guinea. His wound, and an attack of fever, compelled him to return to England to recruit his health, but he reappeared at the front in April 1813. While in England he was invested with the collar and badge of a K.B. by the prince regent, and in June he was made a lieutenant-general in the army. The conduct of the 3rd division under his leadership at the battle of Vittoria and in the engagements in the Pyrenees raised his reputation as a resolute and skilful fighting general to a still higher point. Early in 1814 he was offered, but after consulting Wellington declined, the command of the British forces operating on the side of Catalonia. He thus bore his share in the Orthez campaign and in the final victory before Toulouse.

On the break-up of the division the officers presented Picton with a valuable service of plate, and on the 24th of June 1814 he received for the seventh time the thanks of the House of Commons for his great services. Somewhat to his disappointment he was not included amongst the generals who were raised to the peerage, but early in 1815 he was made a G.C.B. When Napoleon returned from Elba, Picton, at Wellington's request, accepted a high command in the Anglo-Dutch army. He was severely wounded at Quatre Bras on the 16th of June, but concealed his wound and retained command of his troops, and at Waterloo on the 18th, while repulsing with impetuous valour "one of the most serious attacks made by the enemy on our position," he was shot through the head by a musket ball. His body was brought home to London, and buried in the family vault at St George's, Hanover Square. A public monument was erected to his memory in St Paul's Cathedral, by order of parliament, and in 1823 another was erected at Carmarthen by subscription, the king contributing a hundred guineas thereto.

See Robinson's *Life of Sir Thomas Picton* (London, 1836), with which, however, compare Napier's and Oman's histories of the Peninsular War as to controversial points.

PICTOU, a seaport, port of entry, and capital of Pictou county, Nova Scotia, 90 m. N.E. by N. of Halifax, on a branch of the Intercolonial railway. Pop. (1901), 3235. It has several valuable industries, and is the shipping port for the adjacent coal-mines. The Academy, founded in 1818, played an important part in the early educational history of the province, and still enjoys a high reputation.

PICUS, in Roman mythology, originally the woodpecker, the favourite bird and symbol of Mars as the god of both nature and war. He appears later as a spirit of the forests, endowed with the gift of prophecy, haunting springs and streams, with a special sanctuary in a grove on the Aventine. As a god of agriculture, especially connected with manuring the soil, he is called the son of Stercutus (from *stercus*, dung, a name of Saturn). Again, Picus is the first king of Latium, son of Saturn and father of Faunus. Virgil (*Aen.* vii. 170) describes the reception of the ambassadors of Aeneas by Latinus in an ancient temple or palace, containing figures of his divine ancestors, amongst them Picus, famous as an augur and soothsayer. According to Ovid (*Metam.* xiv. 320), Circe, while gathering herbs in the forest, saw the youthful hero out hunting, and immediately fell in love with him. Picus rejected her advances, and the goddess in her anger changed him into a woodpecker, which pecks impotently at the branches of trees, but still retains prophetic powers. The purple cloak which Picus wore fastened by a golden clasp is preserved in the plumage of the bird. In the simplest form of art, he was represented by a wooden pillar surmounted by a woodpecker; later, as a young man with the bird upon his head.

PICUMNUS is merely another form of Picus, and with him is associated his brother and double PILUMNUS. Picumnus, a rustic deity (like Picus) and husband of Pomona, is specially concerned with the manuring of the soil and hence called *Sterquilinus*, while Pilumnus is the inventor of the pounding of grain, so named from the pestle (*pilum*) used by bakers. Under a different aspect, the pair were regarded as the guardians of women in childbed and of new-born children. Before the child was taken up and formally recognized by the father, a couch was set out for them in the atrium, where their presence guarded it from all evil. Augustine (*De civitate dei*, vi. 9) mentions a curious custom: to protect a woman in childbed from possible violence on the part of Silvanus, the assistance of three deities was invoked—Intercidona (the hewer), Pilumnus (the pounder) and Deverra (the sweeper). These deities were symbolically represented by three men who went round the house by night. One smote the threshold with an axe, another with a pestle, the third swept it with a broom—three symbols of culture (for trees were hewn down with the axe, grain pounded with the pestle, and the fruits of the field swept up with the broom) which Silvanus could not endure.

PIDGIN [or PIGEON] **ENGLISH,** the *lingua franca* of the seaports of China, the Straits Settlements in the Far East, consisting in a jargon of corrupted English words with some intermixture of Portuguese and Malay, following Chinese idiomatic usage. It is employed as a means of communication between foreigners and the native Chinese. The word "pidgin" is the Chinese corruption of "business."

PIE. (1) The name of the bird more generally known as the magpie (*q.v.*). The word comes through the French from Lat. *pica* (*q.v.*). It is probably from the black and white or spotted appearance of the bird that the name "pie" or "pye" (Lat. *pica*) was given to the ordinal, a table or calendar which supplemented that which gave the services for the fixed festivals, &c., and pointed out the effect on them of the festivals rendered movable by the changing date of Easter. An English act of 1549 (3 & 4 Edw. VI. c. 10) abolished "pies" with manuals, legends, primers and other service books. The parti-coloured appearance of the magpie also gives rise to the term "piebald," applied to an animal, more particularly a horse, which is marked with large irregular patches of white and black; where the colour is white and some colour other than black, the more appropriate word is "skew-bald," *i.e.* marked with "skew" or irregular patches. (2) A dish made of meat, fish or other ingredients, also of vegetables or fruit, baked in a covering of pastry; in English usage, where "fruit" is the ingredient, the dish is generally called a "tart," except in the case of "apple-pie." The word appears early in the 14th century of meat or fish pies.

The expression "to eat humble-pie," *i.e.* to make an apology, to retract or recant, is a facetious adaptation of "umbles" (O. Fr. *nombles*, connected with Lat. *lumbus*, loin, or *umbilicus*, navel), the inner parts of a deer, to "humble" (Lat. *humilis*, lowly). An "umble-pie," made of the inner parts of a deer or other animal, was once a favourite dish. "Printers' pie," *i.e.* a mass of confused type, is a transferred sense of "pie," the dish, or of "pie," the ordinal, from the difficulty of decipherment.

PIEDMONT (Ital. *Piemonte*; Low Lat. *Pedemons* and *Pedemontium*), a territorial division (*compartimento*) of northern

Italy, bounded N. by Switzerland, W. by France, S. by Liguria, and E. by Lombardy. Physically it may be briefly described as the upper gathering-ground and valley of the river Po, enclosed on all sides except towards the Lombard plain by the vast semicircle of the Pennine, Graian, Cottian, Maritime and Ligurian Alps. In 1859 it was divided into the four provinces of Alessandria, Cuneo, Novara and Torino (Turin). It has an area of 11,340 sq. m. The people are chiefly engaged in agriculture—growing wheat, maize and rice, chestnuts, wine and hemp; in the reeling and throwing of silk and in the manufacture of cotton, woollens and clothing; there are also considerable manufactures at Turin, Savigliano, &c. The Piedmontese dialect has been rather strongly influenced by French. The chief towns in the several provinces are as follows, with their communal populations in 1901: Alessandria (72,109), Asti (39,251), Casale Monferrato (31,370), Novi Ligure (17,868), Tortona (17,419), Acqui (13,940), Valenza (10,956), Ovada (10,284); total of province 825,745, number of communes 343; Cuneo (26,879), Mondovì (18,982), Fossano (18,175), Savigliano (17,340), Saluzzo (16,028), Brà (15,821), Alba (13,637), Boves (10,137); total of province 670,504, number of communes 263; Novara (44,249), Vercelli (30,470), Biella (19,267), Trino (12,138), Borgomanero (10,131); total of province 763,830, number of communes 437; Turin (329,691), Pinerolo (18,039), Carmagnola (11,721), Ivrea (11,696), Moncalieri (11,467); total of province 1,147,414, number of communes 442. The total population of Piedmont was 2,738,814 in 1859, and in 1901 3,407,493. The large number of communes is noticeable, as in Lombardy, and points to a village life which, owing to greater insecurity and the character of the country, is not to be found in central and southern Italy as a whole. There are numerous summer resorts in the Alpine valleys. The chief railway centres are Turin, communicating with the Mont Cenis line, and with the Riviera by the railway over the Col di Tenda (in process of construction), Novara, Vercelli, Asti, Alessandria, Novi. The communications with Liguria are difficult owing to the approach of the mountains to the coast, and the existing lines from Genoa to Turin and Milan are hardly sufficient to cope with the traffic.

Piedmont in Roman times until 49 B.C. formed a part of Gallia Transpadana, and in Augustus' division of Italy formed with what was later known as Lombardy the 11th region. It formed part of the Lombard kingdom, and it was not till about A.D. 1000 that the house of Savoy (*q.v.*) arose. The subsequent history of Piedmont is that of its dynasty.

PIENZA, a town of Tuscany, Italy, in the province of Siena, 9 m. west of the town of Montepulciano by road, 1611 ft. above sea-level. Pop. (1901), 2730 (town); 3836 (commune). The place was originally called Corsignano and owes its present name to Aeneas Silvius Piccolomini, Pope Pius II. (*q.v.*), who was born here in 1405. The buildings which he caused to be erected by Bernardo Rossellino in 1460–1463 form a noble group of early Renaissance architecture round the Piazza del Duomo. The latter retains Gothic details in the interior, but the façade is simple Renaissance work. The other three sides are occupied by the episcopal and municipal palaces, and the Palazzo Piccolomini; the last, resembling the Palazzo Rucellai at Florence, is the finest, and in front of it is a beautiful fountain. The episcopal palace contains a museum with some fine ecclesiastical vestments, enamels and other works of art.

PIER (older forms *per* or *pere*, from Med. Lat. *pera*; the word is of obscure origin, and the connexion with Fr. *pierre*, Lat. *petra*, stone, is doubtful; equivalents are Fr. *piedroit*, *pilier*, *trumeau*; Ital. *pila*; Ger. *Pfeiler*), the term given in architecture to a vertical support in masonry or brickwork, usually rectangular on plan, which carries an arch or superstructure. The term is also sometimes given to the great circular columns which in some English cathedrals and churches carry the nave arches. In early Christian churches, when antique columns, such as abounded in Rome, were not procurable, square piers took the place of columns and sometimes alternated with them. The introduction of vaulting, however, in the 11th century, necessitated a support of much greater dimensions than those which had been deemed sufficient when the roof was of timber only, and led to the development of the compound or clustered pier. To give extra support to the subordinate arches of the nave arcade, semicircular shafts or pilasters were added, carried up to the transverse and diagonal ribs of the main vault. In Romanesque work the pier was generally square on plan with semicircular shafts attached, the angles of the pier being worked with smaller shafts. As the rings or orders of the nave arches increased in number, additional shafts were added to carry them, and the pilaster facing the nave had central and side shafts rising to carry the transverse and diagonal ribs of the vault; this development of the compound pier obtains throughout Europe in all vaulted structures. In the Early English period the piers become loftier and lighter, and in most important buildings a series of clustered columns, frequently of marble, are placed side by side, sometimes set at intervals round a circular centre, and sometimes almost touching each other. These shafts are often wholly detached from the central pier, though grouped round it, in which case they are almost always of Purbeck or Bethersden marbles. In Decorated work the shafts on plan are very often placed round a square set angle-wise, or a lozenge, the long way down the nave; the centre or core itself is often worked into hollows or other mouldings, to show between the shafts, and to form part of the composition. In this and the latter part of the previous style there is generally a fillet on the outer part of the shaft, forming what has been called a "keel moulding" (*q.v.*). They are also often tied together by bands, formed of rings of stone and sometimes of metal. About this period, too, these intermediate mouldings run up into and form part of the arch moulds, there being no impost. This arrangement became much more frequent in the Perpendicular period; in fact it was almost universal, the commonest section being a lozenge set with the long side from the nave to the aisle, and not towards the other arches, as in the Decorated period, with four shafts at the angles, between which were shallow mouldings, one of which was in general a wide hollow, sometimes with wave moulds. The small columns at the jambs of doors and windows, and in arcades, and also those attached to piers or standing detached, are generally called "shafts" (*q.v.*).

The term pier is sometimes applied to the solid parts of a wall between windows or voids, and also to the isolated masses of brickwork or masonry to which gates are hung. (R. P. S.)

Piers of Bridges.—The piers of bridges and viaducts on land are constructed of masonry or brickwork and occasionally, in the case of high piers, of open braced ironwork, as exemplified by the old Crumlin viaduct in Wales and the Pecos viaduct in Texas. These piers, besides being proportioned in cross-section to the weight they have to support, are widened out at their base, so as to distribute the load over a sufficient area for it to be borne by the stratum on which it rests without risk of settlement. Special provisions have to be made for the foundations of piers where the ground is soft for some depth, or loose water-bearing strata are encountered, and especially where the piers of large bridges crossing rivers have to be constructed under water. In soft ground, bearing piles driven down to a firm stratum, and surmounted by a planked floor or a layer of concrete, provide a convenient foundation for a pier; and in places where timber is abundant, wooden cribs filled with rubble stone or concrete have been used in the United States for raising the foundations for piers out of water. For river piers, where a firm, watertight stratum is found at a moderate depth below the river-bed, the site is often enclosed within a coffer-dam or a plate iron caisson carried down into the stratum and raised out of water; and then, after the water has been pumped out and the surface layers removed, the pier is readily built within the enclosure in the open air. When, however, a river-bed consists of silt, sand or other soft materials extending down to a considerable depth, brickwork wells are gradually sunk to a firm stratum by removing the material within them with grabs, and on them the piers are built out of water; or bottomless caissons are carried down by excavating their interiors under compressed air, and the piers are built on top of them within a plate-iron enclosure, a system

adopted for the piers of the Brooklyn, St Louis, Forth and other large bridges, and essential for forming foundations on sloping rock, such as was encountered in places under the Firth of Forth.

The methods indicated above as employed for the foundations of the piers of bridges under favourable conditions belong equally to the foundations of other structures (see FOUNDATIONS); but there are some methods which, by combining bridge piers and their foundations in a single structure, appertain entirely to piers. Thus iron screw piles, sunk by turning into

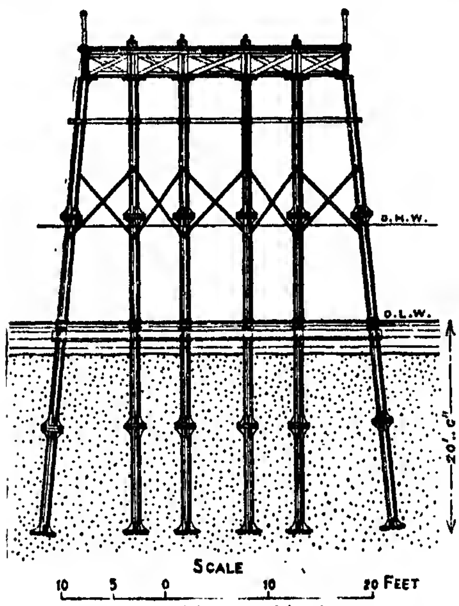

FIG. 1.—Pier with Disk Piles.

the soft bed of a river till they reach a firm stratum or one sufficiently consolidated by the superincumbent layers to enable it to support the wide blades of the screws with the weight imposed on them, were formerly often arranged in converging clusters joined together at the top, so as to serve as the piers of bridges having several comparatively small spans, and intended for carrying lightly constructed railways across rivers in India and elsewhere. Hollow, cast-iron, cylindrical piles also, with a broad circular disk at the bottom to increase their bearing surface, have been used for piers founded in sandy or silty strata of considerable thickness; they are sunk to the requisite depth by lowering a pipe down the inside of the pile to the bottom and emitting a powerful jet of water which, stirring up the soft material and scouring it away from under the disk, causes the pile to descend. This system was first adopted for the piers of a railway viaduct crossing the wide, sandy Kent and Leven estuaries opening into Morecambe Bay (fig. 1). Cast-iron cylinders, consisting of a series of rings formed of segments all bolted together with a specially strong bottom ring, sometimes made of wrought iron and having a cutting edge, have been often employed for the construction of the river piers of bridges, being gradually carried down to a watertight stratum by excavating inside, and subsequently filled up solid with concrete and brickwork; the piers of the Charing Cross and Cannon Street bridges across the Thames are notable instances of the adoption of this method, which is well illustrated by the piers of the bridges across the River Chittravati in India (fig. 2). Sometimes, instead of two or more independent cylinders being sunk, the whole site of a pier is enclosed within a wrought-iron caisson, usually divided into sections by vertical partitions, which is sunk and filled up solid in the same way as cylinders, a system adopted, for instance, for the piers of the bridge across the Hawkesbury River in New South Wales.

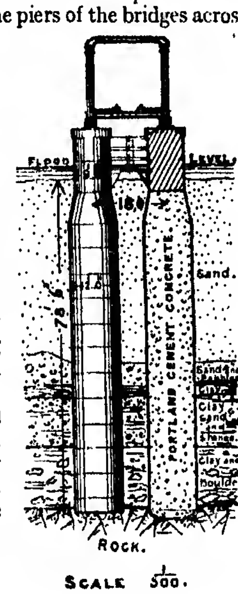

FIG. 2.—Cylindrical Piers for River Bridges.

Promenade Piers.—The term pier is often applied to works sheltering harbours, such as the Tynemouth piers, which are strictly breakwaters. Landing stages also, whether solid or open, have for a long time been called piers, as the Admiralty Pier and the Prince of Wales's Pier at Dover; but the open promenade piers which form a common feature at seaside resorts are the type of pier best known to the general public. These piers are supported upon open pilework of timber or iron, and consequently expose little surface to waves in storms and do not interfere with the drift of shingle or sand along the coast (fig. 3).[1] Timber piles are best suited for withstanding the shocks of vessels at landing stages, at which places they are generally used; but since they are subject to the attacks of the teredo, and expose a considerable surface to the waves, iron piles are generally adopted for the main portion of these piers.

The pioneer of these piers was the old chain pier at Brighton, which was erected in 1822–1823. It was founded upon oak piles, was 1136 ft. long, and had a timber landing-stage at the end. It consisted of four spans suspended from chains on the model of the Menai Suspension Bridge, then in course of construction, and was destroyed by a gale in December 1896. A wider and more modern type of pier was erected at the west end of Brighton in 1865–1866, and subsequently extended; whilst a new pier was completed in 1900 near the site of the old chain pier, 1700 ft. long. The Southport pier, erected in 1859–1860 and afterwards prolonged, furnishes an example of an iron pier supported on disk piles sunk in sand as described above (fig. 1); whilst the much more commonly used iron screw piles, adopted as early as 1847 for an open landing-pier on the Irish coast at Courtown, which was exposed to a great littoral drift of sand, are shown as the mode of support for the pier

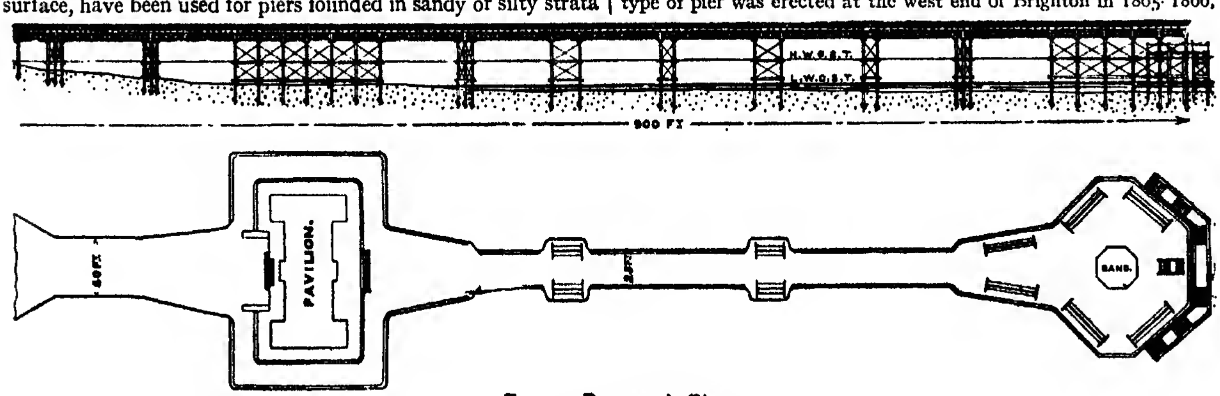

FIG. 3.—Promenade Pier.

[1] *The Engineer* (1888), i. 380, 381 and 384.

at St Leonards (fig. 3). The length given to these promenade piers depends mainly on the slope of the foreshore, which determines the distance from the shore at which a sufficient depth is reached for steamers of moderate draught to come alongside the end of the pier. Thus, whereas a length of 900 ft. has sufficed for the St Leonards pier on a somewhat steep, shingly beach, the pier at Ryde, constituting the principal landing-place for the Isle of Wight passengers, has had to be carried out about half a mile across a flat alluvial foreshore to reach water deep enough for the access of the steamboats crossing the Solent. The vast sands, moreover, at the outlet of the Ribble estuary, stretching two or three miles in front of Southport at low water of spring tides, have necessitated the construction of a pier 4395 ft. long merely to get out to an old flood-tide channel, which is now completely severed by the sands at low water from all connexion with the river.

(L. F. V.-H.)

PIERCE, FRANKLIN (1804–1869), fourteenth president of the United States, was born at Hillsborough, New Hampshire, on the 23rd of November 1804. His father, Benjamin Pierce (1757–1839), served in the American army throughout the War of Independence, was a Democratic member of the New Hampshire House of Representatives from 1789 to 1803, and was governor of the state in 1827–1829. The son graduated in 1824 at Bowdoin College, at Brunswick, Maine, where he formed a friendship with Nathaniel Hawthorne. Pierce then studied law, and in 1827 was admitted to the bar and began to practise at Hillsborough. He at once took a lively interest in politics, and from 1829 to 1833 served in the state House of Representatives, for the last two years as Speaker. In 1833 he entered the national House of Representatives, and although he achieved no distinction in debate he was a hard worker, and a loyal supporter of the policies of President Jackson. After four years in the house he entered the Senate, being its youngest member. In 1842, before the expiration of his term, he resigned his seat, and at Concord, New Hampshire, began his career at the bar in earnest, though still retaining an interest in politics. In 1845 he declined the Democratic nomination for governor, and also an appointment to the seat in the United States Senate made vacant by the resignation of Judge Levi Woodbury. He accepted, however, an appointment as Federal District Attorney for New Hampshire, as the duties of this office, which he held in 1845–1847, were closely related to those of his profession. In 1846 he again declined public honours, when President Polk invited him to enter the cabinet as attorney-general. Soon after the outbreak of the war with Mexico, in 1846, Pierce enlisted as a private at Concord, but soon (in February 1847) became colonel of the Ninth Regiment (which joined General Winfield Scott at Pueblo on the 6th of August 1847), and later (March 1847) became a brigadier-general of volunteers. At the battle of Contreras, on the 19th of August 1847, he was thrown from his horse and received severe injuries. At the end of the war he resigned his commission and returned to Concord. In 1850 Pierce became president of a convention assembled at Concord to revise the constitution of his state, and used his influence to secure the removal of those provisions of the constitution of 1792 which declared that only Protestants should be eligible for higher state offices. This amendment passed the convention in April 1852, but was rejected by the electorate of the state; a similar amendment was adopted by popular vote in 1877. In January 1852 the legislature of New Hampshire proposed him as a candidate for the presidency, and when the Democratic national convention met at Baltimore in the following June the Virginia delegation brought forward his name on the thirty-fifth ballot. Although both parties had declared the Compromise of 1850 a finality, the Democrats alone were thoroughly united in support of this declaration, and therefore seemed to offer the greater prospect of peace. This fact, combined with the colourless record of their candidate, enabled them to sweep the country at the November election. Pierce received 254 electoral votes, and General Winfield Scott, his Whig opponent, only 42. The Democrats carried every state except Massachusetts, Vermont, Kentucky and Tennessee. No president since James Monroe had received such a vote.

Pierce was the youngest man who had as yet been elevated to the presidency. For his cabinet he chose William L. Marcy of New York, secretary of state; Jefferson Davis of Mississippi, secretary of war; James Guthrie (1792–1869) of Kentucky, secretary of the treasury; James C. Dobbin (1814–1857) of North Carolina, secretary of the navy; Robert McClelland (1807–1880) of Michigan, secretary of the interior; James Campbell (1813–1893) of Pennsylvania, postmaster-general; and Caleb Cushing of Massachusetts, attorney-general. This was an able body of men, and is the only cabinet in American history that has continued unbroken throughout an entire administration. Although Pierce during his term in the Senate had severely criticized the Whigs for their removals of Democrats from office, he himself now adopted the policy of replacing Whigs by Democrats, and the country acquiesced. Pierce had no scruples against slavery, and opposed anti-slavery agitation as tending to disrupt the Union. The conduct of foreign relations was on the whole the most creditable part of his administration. The Koszta Affair (1853) gave the government an opportunity vigorously to assert the protection it would afford those in the process of becoming its naturalized citizens. When the British government refused to prevent recruiting for the Crimean War by their representatives in America, their minister, John F. Crampton, received his passports, and the exequaturs of the British consuls at New York, Philadelphia and Cincinnati were revoked. A commercial treaty was negotiated with Japan in 1854 after Perry's expedition in the previous year. As an avowed expansionist, Pierce sympathized with the filibuster government set up in Nicaragua by William Walker, and finally accorded it recognition. It was during this term also that the Gadsden Purchase was consummated, by which 45,535 sq. m. of territory were acquired from Mexico, and that three routes were surveyed for railways from the Mississippi river to the Pacific coast.

When the Democratic national convention met at Cincinnati in June 1856, Pierce was an avowed candidate for renomination, but as his attitude on the slavery question, and especially his subserviency to the South in supporting the pro-slavery party in the Territory of Kansas, had lost him the support of the Northern wing of his party, the nomination went to James Buchanan. After retiring from the presidency Pierce returned to Concord, and soon afterwards went abroad for a three years' tour in Europe. Many Southern leaders desired his renomination by the Democratic party in 1860, but he received such suggestions with disfavour. After his return to America he remained in retirement at Concord until the day of his death, the 8th of October 1869.

Pierce was not a great statesman, and his fame has been overshadowed by that of Benton, Calhoun, Clay and Webster. But he was an able lawyer, an orator of no mean reputation, and a brave soldier. He was a man of fine appearance and courtly manners, and he possessed personal magnetism and the ability to make friends, two qualities that contributed in great measure to his success.

A portion of Pierce's correspondence has been published in the *American Historical Review*, x. 110–127, 350–370. D. W. Bartlett's *Franklin Pierce* (Auburn, New York, 1852) and Nathaniel Hawthorne's *Franklin Pierce* (Boston, 1852) are two "campaign" biographies, and are very eulogistic. J. R. Irelan's *History of the Life, Administration and Times of Franklin Pierce* (Chicago, 1888), being vol. xiv. of his *Republic*, is a more critical work, but inaccurate as to details. J. E. Cooley's *Review of the Administration of General Pierce* (New York, 1854) and Anna E. Carroll's *Review of Pierce's Administration* (Boston, 1856) are hostile anti-administration tracts. The best accounts of Pierce's administration are to be found in James Schouler's *History of the United States*, vol. v. (new ed., New York, 1894); J. F. Rhodes's *History of the United States*, vols. i. and ii. (New York, 1893–1894); and J. W. Burgess's *Middle Period* (New York, 1900).

PIERO DI COSIMO (1462–1521), the name by which the Florentine painter Pietro di Lorenzo is generally known. He was born in Florence about 1462, and worked in the *bottega* of Cosimo Rosselli (from whom he derived his popular name). Other influences that can be traced in his work are those of Filippino Lippi, Luca Signorelli and Leonardo da Vinci, and, as has been recently suggested by Professor R. Muther, that of Hugo van der Goes, whose Portinari altar-piece (now at the

Spedale of S. Maria Novella in Florence) helped to lead the whole of Florentine painting into new channels. From him, most probably, he acquired the love of landscape and the intimate knowledge of the growth of flowers and of animal life. The influence of Hugo van der Goes is especially apparent in the "Adoration of the Shepherds," at the Berlin Museum. He had the gift of a fertile fantastic imagination, which, as a result of a journey to Rome in 1482 with his master, Rosselli, became directed towards the myths of classic antiquity. He proves himself a true child of the Renaissance in such pictures as the "Death of Procris," at the National Gallery, the "Mars and Venus," at the Berlin Gallery, the "Perseus and Andromeda" series, at the Uffizi in Florence, and the "Hylas and the Nymphs" belonging to Mr Benson. If, as we are told by Vasari, he spent the last years of his life in gloomy retirement, the change was probably due to Savonarola, under whose influence he turned his attention once more to religious art. The "Immaculate Conception," at the Uffizi, and the "Holy Family," at Dresden, best illustrate the religious fervour to which he was stimulated by the stern preacher.

With the exception of the landscape background in Rosselli's fresco of the "Sermon on the Mount," in the Sistine Chapel, we have no record of any fresco work from his brush. On the other hand, he enjoyed a great reputation as a portrait-painter, though the only known examples that can be definitely ascribed to him are the portrait of a warrior, at the National Gallery (No. 895), the so-called "Bella Simonetta," at Chantilly, the portraits of Giuliano di San Gallo and his father, at the Hague, and a head of a youth, at Dulwich. Vasari relates that Piero excelled in designing pageants and triumphal processions for the pleasure-loving youths of Florence, and gives a vivid description of one such procession at the end of the carnival of 1507, which illustrated the triumph of death. Piero di Cosimo exercised considerable influence upon his fellow-pupils Albertinelli and Bartolommeo della Porta and was the master of Andrea del Sarto. Examples of his work are also to be found at the Louvre in Paris, the Harrach and Liechtenstein collections in Vienna, the Borghese Gallery in Rome, the Spedale degli Innocenti in Florence, and in the collections of Mr John Burke and Colonel Cornwallis West in London. A "Magdalen" from his brush was added to the National Gallery of Rome in 1907.

See *Piero di Cosimo*, by F. Knapp (Halle, 1899); *Piero di Cosimo*, by H. Haberfeld (Breslau, 1901).

PIERRE, the capital of South Dakota, U.S.A., and the county-seat of Hughes county, situated on the east bank of the Missouri River, opposite the mouth of the Bad River, about 185 m. N.W. of Yankton. Pop. (1910, U.S. census), 3656. Pierre is served by the Chicago & North-Western railway; the Missouri is navigable here, but river traffic has been practically abandoned. Among the principal buildings are the state capitol (1909) and the post office building. Pierre has a public library, and is the seat of the Pierre Industrial School (co-educational, opened in 1890), a government boarding school (non-reservation) for Indian children. The city has a large trade in livestock, and is a cetnre for the mining districts of the Black Hills and for a grain-growing country. Natural gas is used for lighting, heating and power. A fur-trading post, Fort La Framboise, was built in 1817 by a French fur-trader (from whom it took its name) at the mouth of the Teton or Little Missouri River (now called the Bad River), on or near the site of the present village of Fort Pierre (pop. in 1905, 505). In 1822 Fort Tecumseh was built about 2 m. up-stream by the Columbia Fur Company, which turned it over in 1827 to the American Fur Company. The washing away of the river bank caused the abandonment of this post and the erection about a mile farther up-stream, and a short distance west of the river, of Fort Pierre Chouteau (later called Fort Pierre), occupied in 1832, and named in honour of Pierre Chouteau, jun. (1789–1865).[1] For twenty years thereafter Fort Pierre was the chief fur-trading dépôt of the Upper Missouri country. In 1855 the United States government bought the post building and other property for $45,000, and laid out around them a military reservation of about 270 sq. m. The fort was the headquarters of General William S. Harney (1800–1889) in his expedition against the Sioux in 1856, and in March of that year an important council between General Harney and the chiefs of all the Sioux bands, except the Blackfeet, was held here. The fort was abandoned in 1857. Pierre was laid out in 1880, was incorporated as a villag in 1883, and was chartered as a city in 1900.

See Major Frederick T. Wilson, "Fort Pierre and its Neighbors," in *South Dakota Historical Collections*, vol. i. (Aberdeen, S.D., 1902); and Hiram M. Chittenden, *The American Fur Trade of the Far West* (3 vols., New York, 1902).

PIERRE DE CASTELNAU (d. 1208), French ecclesiastic, was born in the diocese of Montpellier. In 1199 he was archdeacon of Maguelonne, and was appointed by Pope Innocent III. as one of the legates for the suppression of heresy in Languedoc. In 1202, when a monk in the Cistercian abbey of Fontfroide, Narbonne, he was designated to similar work, first in Toulouse, and afterwards at Viviers and Montpellier. In 1207 he was in the Rhone valley and in Provence, where he became involved in the strife between the count of Baux and Raymond, count of Toulouse, by one of whose agents he was assassinated on the 15th of January 1208. He was beatified in the year of his death by Pope Innocent III.

See De la Bouillerie, *Le Bienheureux Pierre de Castelnau et les Albigeois au XIII. siècle* (Paris, 1866).

PIERREFONDS, a town of northern France, in the department of Oise, 9 m. S.E. of Compiègne by road. Pop. (1906), 1482. It is celebrated for its feudal stronghold, a masterpiece of modern restoration. The building is rectangular in shape, with a tower at each corner and at the centre of each of the walls, which are strengthened by crenelation and machicolation. A lofty keep defends the principal entrances on the south-west. The interior buildings are chiefly modern, but the exterior reproduces faithfully that of the medieval fortress. Pierrefonds has a church dating from various periods from the 11th to the 16th century, and its mineral springs are in some repute. The château was begun in the last decade of the 14th century by Louis d'Orléans, to whom the domain was given by Charles VI., and finished early in the 15th century. It was subsequently held by the Burgundians, the English and the adherents of the League, from whom it passed to Henry IV. It was dismantled in 1622. The ruins, bought by Napoleon I., were restored, by order of Napoleon III., from 1858 to 1895, under the direction, first of Viollet-le-Duc and afterwards of E. Boeswillwald.

PIERREPONT, WILLIAM (*c.* 1607–1678), English politician, was the second son of Robert Pierrepont, 1st earl of Kingston. Returned to the Long Parliament in 1640 as member for Great Wenlock, he threw his influence on the side of peace and took part for the parliament in the negotiations with Charles I. at Oxford in 1643. Pierrepont was a member of the committee of both kingdoms, and represented the parliamentary party during the deliberations at Uxbridge in 1645; but from that time, according to Clarendon, he forsook his moderate attitude, and "contracted more bitterness and sourness than formerly." This statement, however, is perhaps somewhat exaggerated, as Pierrepont favoured the resumption of negotiations with the king in 1647, and in the following year his efforts on behalf of peace at Newport, where again he represented the parliamentarians, brought upon him some slight censure from Cromwell. For his services at Newport he was thanked by parliament; but he retired from active political life soon afterwards, as he disliked the "purging" of the House of Commons by Colonel Pride and the proceedings against the king. In spite of his

[1] Pierre Chouteau in 1804 succeeded his father, one of the founders of St Louis, in the Missouri Fur Company; and about 1834 Pratt, Chouteau & Company, of which he was the leading member, bought the entire western department of the American Fur Company, and in 1838 reorganized under the name of Pierre Chouteau, jun., & Company. Chouteau built (in 1830–1831) the "Yellowstone," which went up the river to the present site of Pierre in 1831, and was the first steamboat to navigate the upper waters of the Missouri. Chouteau lived for some years in New York City, and while living in St Louis was a member of the convention (1820) which drafted the first constitution of Missouri.

moderate views Pierrepont enjoyed the personal friendship of Cromwell; but, although elected, he would not sit in the parliament of 1656, nor would he take the place offered to him in the Protector's House of Lords. When Richard Cromwell succeeded his father, Pierrepont was an unobtrusive but powerful influence in directing the policy of the government, and after a short period of retirement on Richard's fall he was chosen, early in 1660, a member of the council of state. He represented Nottinghamshire in the Convention Parliament of 1660, and probably was instrumental in saving the lives of some of the parliamentary leaders. At the general election of 1661 he was defeated, and, spending the remainder of his life in retirement, he died in 1678. Pierrepont married Elizabeth, daughter of Sir Thomas Harris, Bart., of Tong Castle, Shropshire, by whom he had five sons and five daughters. His eldest son, Robert (d. 1666), was the father of Robert, 3rd earl, William, 4th earl, and Evelyn, 1st duke of Kingston; and his third son, Gervase (1649–1715), was created in 1714 baron Pierrepont of Hanslope, a title which became extinct on his death.

PIERROT (Ital. *Pedrolino*), the name given to the leading character in the French pantomime plays since the 18th century; transferred from the Italian stage, and revived especially in recent times. He is always in white, both face and costume, with a loose and daintily clownish garb, and is represented as of a freakish disposition. Modern pierrot plays have converted the pierrot into a romantic and even pathetic figure.

PIERSON, HENRY HUGO [properly HENRY HUGH PEARSON], (1815–1873), English composer, was the son of the Rev. Dr Pearson of St John's College, Oxford, where he was born in 1815; his father afterwards became dean of Salisbury. Pierson was educated at Harrow and Trinity College, Cambridge, and was at first intended for the career of medicine. His musical powers were too strong to be repressed, and after receiving instruction from Attwood and A. T. Corfe he went in 1839 to Germany to study under C. H. Rink, Tomaschek and Reissiger. He was elected Reid Professor of Music in Edinburgh in 1844, but, owing to a disagreement with the authorities, he resigned in the following year, and definitely adopted Germany as his country about the same time, making the change in his names noted above. His two operas, *Leila* (Hamburg, 1848) and *Contarini* (Hamburg, 1872), have not retained their hold upon the German public as his music to *Faust* has done, a work which until quite recently was frequently associated with Goethe's drama. He was never recognized in England as he was in Germany, for most of his career fell in the period of the Mendelssohn fashion. His most important work was the oratorio *Jerusalem*, produced at the Norwich Festival of 1852, and subsequently given in London (Sacred Harmonic Society, 1853) and Würzburg (1862). For the Norwich Festival (at one of the meetings a selection from his *Faust* music was given with success) he began an oratorio, *Hezekiah*, in 1869; it was not finished, but was given in a fragmentary condition at the festival of that year. These two large works and a number of Pierson's songs, as well as the three overtures played at the Crystal Palace, reveal undeniable originality and a wealth of melodic ideas. He was weak in contrapuntal skill, and his music was wanting in outline and coherence; but in more fortunate conditions his great gifts might have been turned to better account. He died at Leipzig on the 28th of January 1873, and was buried at Sonning, Berks, of which parish his brother, Canon Pearson, was rector.

PIETAS, in Roman mythology, the personification of the sense of duty towards God and man and the fatherland. According to a well-known story, a young woman in humble circumstances, whose father (or mother) was lying in prison under sentence of death, without food, managed to gain admittance, and fed her parent with milk from her breast. To commemorate her filial affection a temple was dedicated (181 B.C.) by Manius Acilius Glabrio to Pietas in the Forum Holitorium at Rome, on the spot where the young woman had formerly lived. The temple was probably originally vowed by the elder Glabrio out of gratitude for the *pietas* shown during the engagement by his son, who may have saved his life, as the elder Africanus that of his father at the battle of Ticinus (Livy xxi. 46); the legend of the young woman (borrowed from the Greek story of Mycon and Pero, Val. Max. v. 4, ext. 1) was then connected with the temple by the identification of its site with that of the prison. There was another temple of Pietas near the Circus Flaminius, which is connected by Amatucci (*Rivista di storia antica*, 1903) with the story of the *pietas* of C. Flaminius (Val. Max. v. 4, 5), and regarded by him as the real seat of the cult of the goddess, the Pietas of the sanctuary dedicated by Glabrio being a Greek goddess. Pietas is represented on coins as a matron throwing incense on an altar, her attribute being a stork. Typical examples of " piety " are Aeneas and Antoninus Pius, who founded games called Eusebeia at Puteoli in honour of Hadrian.

PIETERMARITZBURG, the capital of Natal, situated in 29° 46′ S., 30° 13′ E., 45 m. in a direct line (71 by rail) W.N.W. of Durban. It lies, 2200 ft. above the sea, north of the River Umsunduzi, and is surrounded by wooded hills. Of these the Town Hill, flat-topped, rises 1600 ft. above the town. Pop. (1904), 31,119, of whom 15,087 were whites, 10,752 Kaffirs, and 5280 Indians. The town is laid out on the usual Dutch South African plan—in rectangular blocks with a central market square. The public buildings include the legislative council chambers and the legislative assembly buildings, government house, the government offices, college, post office and market buildings. The town hall, a fine building in a modified Renaissance style (characteristic of the majority of the other public buildings), has a lofty tower. It was completed in 1901, and replaces a building destroyed by fire in 1898. St Saviour's is the cathedral church of the Anglican community. The headquarters of the Dutch Reformed Church are also in the town. There are monuments of Queen Victoria and Sir Theophilus Shepstone, and various war memorials—one commemorating those who fell in Zululand in 1879, and another those who lost their lives in the Boer War 1899–1902. A large park and botanical gardens add to the attractions of the town. A favourite mode of conveyance is by rickshaw. The climate is healthy and agreeable, the mean annual temperature being 65° F. (55° in June, 71° in February). The rainfall is about 38 in. a year, chiefly in the summer months (Oct.-Mar.), when the heat is tempered by violent thunderstorms.

Pietermaritzburg was founded early in 1839 by the newly-arrived Dutch settlers in Natal, and its name commemorates two of their leaders—Piet Retief and Gerrit Maritz. From the time of its establishment it was the seat of the Volksraad of the Natal Boers, and on the submission of the Boers to the British in 1842 Maritzburg (as it is usually called) became the capital of the country. It was given a municipal board in 1848, and in 1854 was incorporated as a borough. Railway connexion with Durban was made in 1880, and in 1895 the line was extended to Johannesburg. The borough covers 44 sq. m. and includes numerous attractive suburbs. The rateable value is about £4,000,000. Various industries are carried on, including brick-making, tanning, brewing, and cart and wagon building.

See J. F. Ingram, *The Story of an African City* (Maritzburg, 1898).

PIETERSBURG, a town of the Transvaal, capital of the Zoutpansberg district, and 177 m. N.N.E. of Pretoria by rail. Pop. (1904), 3276, of whom 1620 were whites. The town is pleasantly situated, at an elevation of 4200 ft., on a small tributary of the Zand River affluent of the Limpopo, and is the place of most importance in the province north of Pretoria. From it roads run to Klein Lelaba and other gold-mining centres in the neighbourhood, and through it passes the old route to Mashonaland, which crosses the Limpopo at Rhodes Drift. The Zoutpansberg district contains a comparatively dense Kaffir population, and a native newspaper is published at Pietersburg.

PIETISM, a movement in the Lutheran Church, which arose towards the end of the 17th and continued during the first half of the following century. The name of Pietists was given to the adherents of the movement by its enemies as a term of ridicule, like that of "Methodists" somewhat later in England. The Lutheran Church had, in continuing Melanchthon's attempt to construct the evangelical faith as a doctrinal system, by the 17th century become a creed-bound theological and sacramentarian institution, which orthodox theologians like Johann Gerhard of Jena (d. 1637) ruled with almost the absolutism of the papacy. Christian faith had been dismissed from its seat in the heart, where Luther had placed it, to the cold regions of the intellect. The dogmatic formularies of the Lutheran Church had usurped the position which Luther himself had assigned to the Bible alone, and as a consequence only they were studied and preached, while the Bible was neglected in the family, the study, the pulpit and the university. Instead of advocating the priesthood of all believers, the Lutheran pastors had made themselves a despotic hierarchy, while they neglected their practical pastoral work. In the Reformed Church, on the other hand, the influence of Calvin had made less for doctrine than the practical formation of Christian life. The presbyterian constitution gave the people a share in church life which the Lutherans lacked, but it involved a dogmatic legalism which imperilled Christian freedom and fostered self-righteousness.

As forerunners of the Pietists in the strict sense, not a few earnest and powerful voices had been heard bewailing the shortcomings of the Church and advocating a revival of practical and devout Christianity. Amongst them were Jakob Boehme (Behmen), the theosophic mystic; Johann Arndt, whose work on *True Christianity* became widely known and appreciated; Heinrich Müller, who described the font, the pulpit, the confessional and the altar as the four dumb idols of the Lutheran Church; the theologian, Johann Valentin Andrea, the court chaplain of the landgrave of Hesse; Schuppius, who sought to restore to the Bible its place in the pulpit; and Theophilus Grossgebauer (d. 1661) of Rostock, who from his pulpit and by his writings raised "the alarm cry of a watchman in Sion." The direct originator of the movement was Philip Jacob Spener, who combined the Lutheran emphasis on Biblical doctrine with the Reformed tendency to vigorous Christian life. Born at Rappolsweiler, in Alsace, on the 13th of January 1635, trained by a devout godmother, who used books of devotion like Arndt's *True Christianity*, accustomed to hear the sermons of a pastor who preached the Bible more than the Lutheran creeds, Spener was early convinced of the necessity of a moral and religious reformation of the German Church. He studied theology, with a view to the Christian ministry, at Strassburg, where the professors at the time (and especially Sebastian Schmidt) were more inclined to practical Christianity than to theological disputation. He afterwards spent a year in Geneva, and was powerfully influenced by the strict moral life and rigid ecclesiastical discipline prevalent there, and also by the preaching and the piety of the Waldensian professor, Antoine Leger, and the converted Jesuit preacher, Jean de Labadie.[1] During a stay in Tübingen he read Grossgebauer's *Alarm Cry*, and in 1666 he entered upon his first pastoral charge at Frankfort-on-the-Main, profoundly impressed with a sense of the danger of the Christian life being sacrificed to zeal for rigid orthodoxy. Pietism, as a distinct movement in the German Church, was then originated by Spener by religious meetings at his house (*collegia pietatis*), at which he repeated his sermons, expounded passages of the New Testament, and induced those present to join in conversation on religious questions that arose. They gave rise to the name "Pietists." In 1675 Spener published his *Pia desideria*, or *Earnest Desires for a Reform of the True Evangelical Church*. In this publication he made six proposals as the best means of restoring the life of the Church: (1) the earnest and thorough study of the Bible in private meetings, *ecclesiolae in ecclesia*; (2) the Christian priesthood being universal, the laity should share in the spiritual government of the Church; (3) a knowledge of Christianity must be attended by the practice of it as its indispensable sign and supplement; (4) instead of merely didactic, and often bitter, attacks on the heterodox and unbelievers, a sympathetic and kindly treatment of them; (5) a reorganization of the theological training of the universities, giving more prominence to the devotional life; and (6) a different style of preaching, namely, in the place of pleasing rhetoric, the implanting of Christianity in the inner or new man, the soul of which is faith, and its effects the fruits of life. This work produced a great impression throughout Germany, and although large numbers of the orthodox Lutheran theologians and pastors were deeply offended by Spener's book, its complaints and its demands were both too well justified to admit of their being point-blank denied. A large number of pastors at once practically adopted Spener's proposals. In Paul Gerhardt the movement found a singer whose hymns are genuine folk poetry. In 1686 Spener accepted an appointment to the court-chaplaincy at Dresden, which opened to him a wider though more difficult sphere of labour. In Leipzig a society of young theologians was formed under his influence for the learned study and devout application of the Bible. Three *magistri* belonging to that society, one of whom was August Hermann Francke, subsequently the founder of the famous orphanage at Halle (1695), commenced courses of expository lectures on the Scriptures of a practical and devotional character, and in the German language, which were zealously frequented by both students and townsmen. The lectures aroused, however, the ill-will of the other theologians and pastors of Leipzig, and Francke and his friends left the city, and with the aid of Christian Thomasius and Spener founded the new university of Halle. The theological chairs in the new university were filled in complete conformity with Spener's proposals. The main difference between the new Pietistic school and the orthodox Lutherans arose from the conception of Christianity as chiefly consisting in a change of heart and consequent holiness of life, while the orthodox Lutherans of the time made it to consist mainly in correctness of doctrine.

[1] Labadie had formed the ascetic and mystic sect of "The Regenerati" in the Church of Holland (*c.* 1660), and then in other parts of the Reformed Church.

Spener died in 1705; but the movement, guided by Francke, fertilized from Halle the whole of Middle and North Germany. Among its greatest achievements, apart from the philanthropic institutions founded at Halle, were the organization of the Moravian Church in 1727 by Count von Zingendorf, Spener's godson and a pupil in the Halle Orphanage, and the establishment of the great Protestant missions, Ziegenbalg and others being the pioneers of an enterprise which until this time Protestantism had strangely neglected.

Pietism, of course, had its weaknesses. The very earnestness with which Spener had insisted on the necessity of a new birth, and on a separation of Christians from the world, led to exaggeration and fanaticism among followers less distinguished than himself for wisdom and moderation. Many Pietists soon maintained that the new birth must always be preceded by agonies of repentance, and that only a regenerated theologian could teach theology, while the whole school shunned all common worldly amusements, such as dancing, the theatre, and public games. There thus arose a new form of justification by works. Its *ecclesiolae in ecclesia* also weakened the power and meaning of church organization. Through these extravagances a reactionary movement arose at the beginning of the 18th century, one of the most distinguished leaders of which was Loescher, superintendent at Dresden.

As a distinct movement Pietism had run its course before the middle of the 18th century; by its very individualism it had helped to prepare the way for another great movement, the Illumination (*Aufklärung*), which was now to lead the world into new paths. Yet Pietism could claim to have contributed largely to the revival of Biblical studies in Germany, and to have made religion once more an affair of the heart and the life, and not merely of the intellect. It likewise vindicated afresh the rights of the Christian laity in regard to their own beliefs and

the work of the Church, against the assumptions and despotism of an arrogant clergy. "It was," says Rudolf Sohm, "the last great surge of the waves of the ecclesiastical movement begun by the Reformation; it was the completion and the final form of the Protestantism created by the Reformation. Then came a time when another intellectual power took possession of the minds of men."

Some writers on the history of Pietism—*e.g.* Heppe and Ritschl—have included under it nearly all religious tendencies amongst Protestants of the last three centuries in the direction of a more serious cultivation of personal piety than that prevalent in the various established churches. Ritschl, too, treats Pietism as a retrograde movement of Christian life towards Catholicism. Some historians also speak of a later or modern Pietism, characterizing thereby a party in the German Church which was probably at first influenced by some remains of Spener's Pietism in Westphalia, on the Rhine, in Wurttemberg, and at Halle and Berlin. The party was chiefly distinguished by its opposition to an independent scientific study of theology, its principal theological leader being Hengstenberg, and its chief literary organ the *Evangelische Kirchenzeitung*. The party originated at the close of the wars with Napoleon I.

Amongst older works on Pietism are J. G. Walch, *Historische und theologische Einleitung in die Religionsstreitigkeiten der evangelisch-Lutherischen Kirche* (1730); A. Tholuck, *Geschichte des Pietismus und des ersten Stadiums der Aufklärung* (1865); H. Schmid, *Die Geschichte des Pietismus* (1863); M. Goebel, *Geschichte des christlichen Lebens in der Rheinisch-Westfälischen Kirche* (3 vols., 1849-1860); and the subject is dealt with at length in J. A. Dorner's and W. Gass's *Histories* of Protestant theology. More recent are Heppe's *Geschichte des Pietismus und der Mystik in der reformirten Kirche* (1879), which is sympathetic; A. Ritschl's *Geschichte des Pietismus* (3 vols., 1880-1886), which is hostile; and C. Sachsse, *Ursprung und Wesen des Pietismus* (1884). See also Fr. Nippold's article in *Theol. Stud. und Kritiken* (1882). pp. 347-392; H. von Schubert, *Outlines of Church History*, ch. xv. (Eng. trans., 1907); and Carl Mirbt's article, "Pietismus," in Herzog-Hauck's *Realencyklopädie, für prot. Theologie u. Kirche*, end of vol. xv.

PIETRO DELLA VIGNA, or PIER DELLE VIGNE [PETRUS DE VINEAS or DE VINEIS] (*c.* 1190–1249), chancellor and secretary to the emperor Frederick II., was born at Capua in humble circumstances. He studied law at Padua, and through his classical education, his ability to speak Latin and his poetic gifts, he gained the favour of Frederick II., who made him his secretary, and afterwards *judex magnae curiae*, councillor, governor of Apulia, prothonotary and chancellor. The emperor, "of whose heart he held the keys," as Dante says, sent him to Rome in 1232 and 1237 to negotiate with the pope, to Padua in 1239 to induce the citizens to accept imperial protection, to England in 1234-1235 to arrange a marriage between Frederick and Isabella, sister of King Henry III. He proved a skilful and trustworthy diplomat, and he persistently defended the emperor against his traducers and against the pope's menaces. But at the Council of Lyons, which had been summoned by Pope Innocent IV., Pietro della Vigna entrusted the defence of his master to the celebrated jurist Taddeo of Suessa, who failed to prevent his condemnation. Frederick, whose suspicions had been awakened by the slanders of the envious, had him imprisoned and blinded without giving him a chance to rebut his accusers. Unable to bear his disgrace, he committed suicide in his prison at Pisa in 1249. The exact date, place and manner of his death are, however, subject to controversy, and Flaminio del Borgo states that it occurred in the church of S. Andrea, at Pisa, in 1256. The tragic fate of this man gave rise to many legends. The Guelphic tradition accuses Pietro della Vigna, as well as the emperor and the court, of heresy; it was even stated, probably without any foundation, that they were the authors of the famous work, *De tribus impostoribus*, wherein Moses, Christ and Mahomet are blasphemed.

Pietro della Vigna was a man of great culture; he encouraged science and the fine arts, and contributed much to the welfare of Italy by wise legislative reforms. He was the author of some delicate verse in the vernacular tongue, of which two *canzoni* and a sonnet are still extant. His letters, mostly written in the name of the emperor and published by Iselin (*Epistolarum libri vi.*, 2 vols., Basel, 1740), contain much valuable information on the history and culture of the 13th century. A collection of the laws of Sicily, a *Tractatus de potestate imperiali*, and another treatise, "On Consolation," in the style of Boëthius, are also attributed to him.

See Huillard-Bréholles, *Vie et correspondance de Pierre de la Vigne* (Paris, 1864); Presta, *Pier delle Vigne* (Milan, 1880); Capasso and Ianelli, *Pier delle Vigne* (Caserta, 1882); also FREDERICK II.

PIG (a word of obscure origin, connected with the Low Ger. and Dut. word of the same meaning, *bigge*), a common name given to the domesticated swine of agricultural use. (For the zoology, see SWINE.)

British breeds of pigs are classified as black, white and red. In some places, notably Wales and Gloucester, a remnant of a spotted breed lingers; and a large proportion of common pigs, often parti-coloured, are mongrels. The white breeds are liable to sun-scald, and black pigs (like black men) are much better adapted than white to exposure in strong sunlight, conforming o the rule that animals in the tropics have black skins.

The *Large Whites* may have in the skin a few blue spots which grow white hair. The head is long, light in the jowl, and wide between the eyes, with long thin ears inclined slightly forward and fringed with long fine hair. The neck is long, but not coarse, the ribs are deep, the loin wide and level, the tail set high, and the legs straight and set well outside the carcase. The whole body, including the back of the neck, is covered with straight silky hair, which denotes quality and lean meat. Pigs of this breed are very prolific, and they may be grown to enormous weights—over 11 cwt. alive.

The *Middle Whites* are built on a smaller scale than the Large Whites. They are shorter in the heads and legs, and fuller at the jowl, thicker and more compact in the body. The sows are quite as prolific as those of the Large White breed, and, as their produce matures earlier, they are much in demand for breeding porkers.

The *Small White* pigs are beautifully proportioned. The head and legs are very short, and the body short, thick and wide; the jowl is heavy, the ears pricked, and the thin skin laden with long silky, wavy, but not curly, hair, whilst the tail is very fine. A deficiency of lean meat is a common characteristic of the breed, which is almost extinct.

The above three breeds were designated Yorkshire Whites, and are still so named at times. The Middle White, formed by crossing the large and the small breeds, is not so symmetrical as the parent stocks, and the type is not uniform.

The *Lincolnshire Curly Coated* or *Boston* pig is a local breed of great size and capacity for producing pork. It is very hardy and prolific, but somewhat coarse in the bone. It has an abundance of long curly hair, a short face and a straight nose, and the ears, not too long and heavy, fall over the face. It crosses well with the Large White, the Large Black and the Berkshire.

The *Large Black* breed, which vies with the Large White breed for size, and is probably its superior as a bacon pig, has only since 1900 received national show-yard recognition; but there is ample evidence that, with its characteristic whole black colour with a mealy hue, length, fine hair and lop ear, the Large Black existed in the south of England for generations. It has been continuously and carefully bred in Cornwall, Devon, Essex and Suffolk, and from these centres it has rapidly spread all over the country. Large Blacks are exceedingly docile, and the ears, hanging well forward over the eyes, contribute materially to a quietness of habit which renders them peculiarly adapted to field grazing. On account of their hardiness and disposition to early maturity they have proved valuable for crossing purposes. The Large Black Pig Society was incorporated in 1899.

The *Berkshire* is a black pig with a pinkish skin, and a little white on the nose, forehead, pasterns, and tip to the tail. It has a moderately short head with heavy jowl, a deep, compact carcase, and wide, low and well-developed hind-quarters, with heavy hams. The skin carries an abundance of fine hair. The Berkshire is an early-maturity breed which has been somewhat

inbred, and is not so hardy and prolific as most breeds. The boars cross well with common stock. It merits the most credit in raising the quality of Irish pigs. In America it is in the front rank for numbers and quality as a lard-hog. There it often grows to be a larger and finer animal than it is in England.

The *Small Black* or *Black Suffolk* was produced from the old Essex pig by crossing with the Neapolitan. It resembles the Small White, except that the skin is coal-black in colour, and the coat of hair is not usually profuse. The Small Black, moreover, is rather longer, and stands somewhat higher, whilst it yields more lean meat than the Small White. It matures early and is quick to fatten.

The *Tamworth* is one of the oldest breeds of pigs. It is hardy, active and prolific, and nearly related to the wild boar. The colour is red or chestnut, with at times darkish spots on the skin. The head, body and legs are long, and the ribs deep and flat. Originally a local breed in the districts around the Staffordshire town from which it takes its name, it is now extensively bred, and highly valued as a bacon pig. (W. Fr.; R. W.)

In America nearly all the breeds may be classified as lard-hogs. Bacon-pigs fed on Indian corn degenerate into lard-hogs, run down in size and become too small in the bone and less prolific by inbreeding.

The *Poland-China*, the most popular breed in the United States, is thus degenerating. It is a black pig like the Berkshire, but has short lop-ears, a more pointed, straight nose, a more compact body, and more white markings. It is a breed of mixed blood, and is believed to have originated from the "Big China" pig—a large white hog with sandy spots, taken to Ohio in 1816, and blended with Irish graziers in 1839, and with a breed known as Bayfields, as well as with Berkshires. In Iowa the Berkshire is a combined lard and bacon pig in high favour.

The *Duroc Jersey* or *Duroc*, of a red or cherry-red colour—not sandy or dark—is the most popular pig in Nebraska and equal to any other in Iowa. It is a large prolific lard-hog, easily making 300 ℔ in eight months. It has gained rapidly in popularity since the beginning of this century, and is spreading to other centres.

The *Chester White*, named from Chester county, Pennsylvania, is one of the four leading breeds of lard-hogs in America. It is of mixed origin and bears a strong family resemblance to the Lincolnshire curly-coated pig. The early English ancestors, the breed of which is not on record in America, were most probably of Lincoln origin. The sow is a prolific breeder and good mother, weighing, when mature but not fat, 450 ℔—the boar averaging 600 ℔, and barrows at six to eight months 350 ℔. At Vermont Station, in a 127 days' test, Chester Whites made an average gain of 1·36 ℔ and dressed 84·5 % carcase, and they can gain fully 1 ℔ of live weight for 3 ℔ of grain consumed.

Management.—The brood sow should be lengthy and of a prolific strain, known to milk well. She is moderately fed and put to a boar of her own age when large enough, *i.e.* seven to eight months old. She remains in a state of oestrum for about three days, and if not pregnant comes in heat again in three weeks. Breeding swine, male and female, run most of their time at pasture and receive a liberal allowance of green food or raw roots. The period of gestation is sixteen weeks. Six to eight pigs are reared of the first litter, and ten to twelve afterwards. Many brood sows are fattened to greatest profit after the second or third litter. Two litters are produced in one year, as pigs are usually weaned at two months old, and the sow will take the boar at from three days to a week after the pigs are removed, according to condition. A convenient sty to hold five or six pigs has a southern aspect, and consists of a covered compartment and outer court, each 10 ft. square. When the animals are fed outside the inner court is kept clean and dry, and there the pigs lie. The labouring man's pig is his bank, and is fed on scraps, small potatoes and waste products. In connexion with cheese dairies pigs are largely fed on sour whey thickened with mixed meal produced from any or all of the grains or pulses, the choice depending upon the market price. Food may with advantage be cooked for very young pigs; but, with the exception of potatoes, which should never be given raw, roots and meals are best given uncooked. Meal mixed with pulped roots for a few hours improves in digestibility, and a sprinkling of salt is an improvement. Meal derived from leguminous seeds makes the flesh firm and improves the quality. Fattening pigs are fed three times a day and supplied with coal-ashes or a few handfuls of earth. Of the fatted live weight of a pig 83 % is butcher's carcase, and 91 % of the increase from 100 to 200 ℔ is carcase. From 3 to 5 ℔ of meal consumed results in an increase of 1 ℔ of live weight in a pig, which is the most economical meat producer on a farm. Concentrated and digestible foods give best results, a pig has a small stomach. Fjord's Danish experiments show that for fattening pigs 1 ℔ of rye- or barley-meal is equivalent to 6 ℔ of skim-milk or 12 ℔ of whey, and 1 ℔ of meal equivalent to 8 ℔ of mangolds or 4 ℔ of potatoes.

PIGALLE, JEAN BAPTISTE (1714–1785), French sculptor, was born in Paris on the 26th of January 1714. He was the seventh child of a carpenter. Although he failed to obtain the *grand prix*, after a severe struggle he entered the Academy and became one of the most popular sculptors of his day. His earlier work, such as "Child with Cage" (model at Sèvres) and "Mercury Fastening his Sandals" (Berlin, and lead cast in Louvre), is less commonplace than that of his maturer years, but his nude statue of Voltaire, dated 1776 (Institut), and his tombs of Comte d'Harcourt (*c.* 1764) (Notre Dame) and of Marshal Saxe, completed in 1777 (Lutheran church, Strassburg), are good specimens of French sculpture in the 18th century. He died on the 28th of August 1785.

See P. Tarbé, *Vie et œuv. de Pigalle* (1859); Suard, *Éloge de Pigalle; Mélanges de littérature.*

PIGAULT-LEBRUN (Pigault de l'Epinoy), **CHARLES ANTOINE GUILLAUME** (1753–1835), French novelist, was born at Calais (he is said to have traced his pedigree on the mother's side to Eustache de St Pierre) on the 8th of April 1753. His youth was stormy. He twice carried off young ladies of some position, and was in consequence twice imprisoned by *lettre de cachet*. The first, a Miss Crawford, the daughter of an English merchant whose office Pigault had entered, died almost immediately after her elopement; the second, Mlle de Salens, he married. He became a soldier in the Queen's Guards, then a very unsuccessful actor, and a teacher of French. At the breaking out of the great war he re-enlisted and fought at Valmy. He wrote more than twenty plays, and a large number of novels, the first of which appeared in 1787. In his old age he took to graver work, and executed an abridgment of French history in eight volumes, besides some other work. His *Œuvres complètes* were published in twenty volumes between 1822 and 1824, but much of his work is subsequent to this collection. He died on the 24th of July 1835. The style of Pigault's novels is insignificant, and their morality very far from severe. As almost the father of a kind of literature which later developed enormously, Pigault-Lebrun deserves a certain place in literary history. Among the most celebrated of his novels may be mentioned *L'Enfant du Carnaval* (1792) and *Angélique et Jeanneton de la place Maubert* (1799). His *Citateur* (2 vols., 1803), a collection of quotations against Christianity, was forbidden and yet several times reprinted.

PIGEON (Fr. *pigeon*, Ital. *piccione* and *pipione*, Lat. *pipio*, literally a nestling-bird that pipes or cries out, a "piper"—the very name now in use among some pigeon-fanciers, though "squeaker" is the more usual term). The name pigeon, doubtless of Norman introduction as a polite term, seems to bear much the same relation to dove, the word of Anglo-Saxon origin, that mutton has to sheep, beef to ox, veal to calf, and pork to bacon; no sharp zoological distinction can be drawn (see Dove) between dove and pigeon, and the collective members of the group *Columbae* are by ornithologists ordinarily called pigeons. Perhaps the best-known species to which the latter name is exclusively given in common speech[1] is the wild pigeon

[1] It may be observed that the "rock-pigeons" of Anglo-Indians are Sand-grouse (*q.v.*), and the "Cape pigeon" of sailors is a petrel (*q.v.*).

or passenger pigeon of North America, *Ectopistes migrarius*, which is still found in many parts of Canada and the United States, though now almost extinct and never appearing in the countless numbers that it did of old, when a flock seen by A. Wilson was estimated to consist of more than 2230 millions. The often-quoted descriptions given by him and J. J. Audubon of pigeon-haunts in the then "backwoods" of Kentucky, Ohio and Indiana need not here be reproduced. That of the latter was declared by C. Waterton to be a gross exaggeration; but the critic would certainly have changed his tone had he known that, some hundred and fifty years earlier, passenger-pigeons so swarmed and ravaged the colonists' crops near Montreal that a bishop of his own church was constrained to exorcise them with holy water, as if they had been demons.[1] The passenger-pigeon is about the size of a common turtle-dove, but with a long, wedge-shaped tail. The male is of a dark slate-colour above, and purplish-bay beneath, the sides of the neck being enlivened by violet, green and gold. The female is drab-coloured above and dull white beneath, with only a slight trace of the brilliant neck-markings.[2] (See plate illustration under DOVE.)

Among the multitudinous forms of pigeons very few can here be noticed. A species which might possibly repay the trouble of domestication is the wonga-wonga or white-fleshed pigeon of Australia, *Leucosarcia picata*, a bird larger than the ring-dove, of a slaty-blue colour above and white beneath, streaked on the flanks with black. It is known to breed, though not very freely, in captivity, and is said to be excellent for the table. As regards flavour, the fruit-pigeons of the genus *Treron* (or *Vinago* of some authors) and its allies surpass all birds. These inhabit tropical Africa, India, and especially the Malay Archipelago; but the probability of domesticating any of them is very remote. Hardly less esteemed are the pigeons of the genus *Ptilopus* and its kindred forms, which have their headquarters in the Pacific Islands, though some occur far to the westward and also in Australia. There may be mentioned the strange Nicobar pigeon, *Caloenas* (see plate illustration under DOVE), an inhabitant of the Indian Archipelago, not less remarkable for the long lustrous hackles with which its neck is clothed than for the structure of its gizzard, which has been described by Sir W. H. Flower (*Proc. Zool. Soc.*, 1860, p. 330), though this peculiarity is matched or even surpassed by that of the same organ in the *Phaenorrhina goliath* of New Caledonia (*Rev. de zoologie*, 1862, p. 138) and in the *Carpophaga latrans* of Fiji. In this last the surface of the epithelial lining is beset by horny conical processes, adapted, it is believed, for crushing the very hard fruits of *Onocarpus vitiensis* on which the bird feeds (*Proc. Zool. Soc.*, 1878, p. 102). The modern giants of the group, consisting of about half a dozen species of the genus *Goura* and known as crowned pigeons (see plate illustration under DOVE), belong to New Guinea and the neighbouring islands, and are conspicuous by their large size, beautiful filmy fan-shaped crest, and the reticulated instead of scutellated covering of their "tarsi."

A very distinct type of pigeon is that represented by *Didunculus strigirostris*, the "Manu-mea" of Samoa, still believed by some to be the next of kin to the Dodo (*q.v.*), but really presenting only a superficial resemblance in the shape of its bill to that extinct form, from which it differs osteologically quite as much as do other pigeons (*Phil. Trans.*, 1869, p. 349). It remains to be seen whether the Papuan genus *Otidiphaps*, of which several species are now known, may not belong rather to the Didunculidae than to the true Columbidae.

Pigeons are now regarded as belonging to the Charadriiform or plover-like birds (see BIRDS) and are placed in the sub-order Columbae, near the sand-grouse (*q.v.*). They are divided into three families, Dididae, which includes the Dodo (*q.v.*) and *Solitaire*, the Columbidae, which includes the doves and pigeons, and the Didunculidae, of which the curious tooth-billed pigeon, of Samoa is the only example. The body is always compact, and the bill has a soft skin or cere covering the nostrils. The pigeons are chiefly vegetable feeders and have a hard gizzard, and all drink much water; they perch, and have a note of the nature of a "coo." The nest is a rough platform or is in holes on the ground or in rocks. The eggs are two or three and white, and the young, which are helpless when hatched, are fed by a secretion from the crop of the parents. (A. N.)

[1] *Voyages du Baron de la Hontan dans l'Amérique septentrionale*, i. 93, 94 (2nd ed., Amsterdam, 1705). In the first edition, published at the Hague in 1703, the passage, less explicit in details but to the same effect, is at p. 80. The author's letter, describing the circumstance, is dated May 1687.

[2] There are several records of the occurrence in Britain of this pigeon, but in most cases the birds noticed cannot be supposed to have found their own way hither. One, which was shot in Fife in 1825, may, however, have crossed the Atlantic unassisted by man.

PIGEON-FLYING, the sport of racing homing-pigeons bred and trained for the purpose. It is of very recent date, although the use of birds as a means of carrying messages (see PIGEON POST) is of great antiquity. Belgium may be considered as *par excellence* the home of the sport, the first birds flown there probably coming from Holland. Long-distance flying began in 1818, with a match of 100 m., while in 1820 there was a race from Paris to Liége, and three years later the first race from London to Belgium. The sport is now a favourite one in Great Britain, the United States, France, and, to a less degree, in some other countries, although nowhere attaining the general popularity which it enjoys in Belgium, where nearly every village has its *Société colombophile*, millions of pigeons being sent over the French border to be raced back. The annual Belgian *concours national*, a race of about 500 m. from Toulouse to Brussels, was inaugurated in 1881, in which year the first regular races in Great Britain, from Exeter, Plymouth and Penzance to London, took place. The velocity attained at that time was about 1250 yds. per minute, but this was soon surpassed in the races of the London Columbarian Society, one of the winners in which attained a speed of 1836 yds. per minute.

The sport was introduced into the United States about the year 1875, although regular racing did not begin until 1878. Since then it has gained widespread popularity, the American record for old birds at 300 m. being 1848 yds. per minute and for young birds (yearlings) 1665 yds., while the distance record is 1004 m. The American "blue ribbon" championships are held at 100, 200, 300, 400, 500 and 600 m. The speed of homing-pigeons depends very greatly upon the state of the atmosphere. In the race from Montargis to Brussels in 1876 in bright and clear weather, all the prize-winners made the distance of 270 m. within three and one-quarter hours, while in the same race in 1877, on a thick and stormy day, thirty hours passed before the first bird arrived.

Training.—The loft should be on a commanding site. It is best made in the shape of a large room, suitably subdivided, protected from vermin, and provided with drinking troughs, rock salt and crushed mortar for the birds' use. It should be fitted with a sufficient number of nests about 2 ft. long, 20 in. in breadth and height. Arrangements should be made for allowing the pigeons to fly out daily for exercise; and they should be trained to re-enter the loft through bolting wires, which open inwards only, into a small chamber, to which an electric arrangement may be fitted so as to sound a bell and warn the owner of the arrival of a bird. The food of birds in training consists of vetch, beans, maize, peas, broken rice and millet, in various proportions, according to the country, climate and season of the year, the daily allowance for each bird being about 40 grammes weight. Young birds may be fed on rice in the husk and bread. They are called "squealers" for a week or two after birth, and then "squeakers" until about three months old. Each brood consists of two eggs, on which both parents sit in turn, the cock only for a few hours in the middle of the day. When the young are being brought up, only one of the parent birds is taken out at a time. One meal per day, given before the birds are let out in the morning, is sufficient. Training should commence in warm weather, when the bird is about four months old, and it consists in taking it out in a closed wicker basket and liberating or "tossing" it at gradually increasing distances from its loft, with several days interval of rest between the flights. The usual preliminary distances are 1, 2, 5, 10 and 15 or 20 m. These tosses should all be made on the same line between the loft and, say, some neighbouring city, in order that a bird may always have to fly in the same general direction during the season. About 100 m. may be expected of birds the first season; they reach their full distances only about the fifth year. It is considered better to

inbred, and is not so hardy and prolific as most breeds. The boars cross well with common stock. It merits the most credit in raising the quality of Irish pigs. In America it is in the front rank for numbers and quality as a lard-hog. There it often grows to be a larger and finer animal than it is in England.

The *Small Black* or *Black Suffolk* was produced from the old Essex pig by crossing with the Neapolitan. It resembles the Small White, except that the skin is coal-black in colour, and the coat of hair is not usually profuse. The Small Black, moreover, is rather longer, and stands somewhat higher, whilst it yields more lean meat than the Small White. It matures early and is quick to fatten.

The *Tamworth* is one of the oldest breeds of pigs. It is hardy, active and prolific, and nearly related to the wild boar. The colour is red or chestnut, with at times darkish spots on the skin. The head, body and legs are long, and the ribs deep and flat. Originally a local breed in the districts around the Staffordshire town from which it takes its name, it is now extensively bred, and highly valued as a bacon pig. (W. Fr.; R. W.)

In America nearly all the breeds may be classified as lard-hogs. Bacon-pigs fed on Indian corn degenerate into lard-hogs, run down in size and become too small in the bone and less prolific by inbreeding.

The *Poland-China*, the most popular breed in the United States, is thus degenerating. It is a black pig like the Berkshire, but has short lop-ears, a more pointed, straight nose, a more compact body, and more white markings. It is a breed of mixed blood, and is believed to have originated from the "Big China" pig—a large white hog with sandy spots, taken to Ohio in 1816, and blended with Irish graziers in 1839, and with a breed known as Bayfields, as well as with Berkshires. In Iowa the Berkshire is a combined lard and bacon pig in high favour.

The *Duroc Jersey* or *Duroc*, of a red or cherry-red colour—not sandy or dark—is the most popular pig in Nebraska and equal to any other in Iowa. It is a large prolific lard-hog, easily making 300 ℔ in eight months. It has gained rapidly in popularity since the beginning of this century, and is spreading to other centres.

The *Chester White*, named from Chester county, Pennsylvania, is one of the four leading breeds of lard-hogs in America. It is of mixed origin and bears a strong family resemblance to the Lincolnshire curly-coated pig. The early English ancestors, the breed of which is not on record in America, were most probably of Lincoln origin. The sow is a prolific breeder and good mother, weighing, when mature but not fat, 450 ℔—the boar averaging 600 ℔, and barrows at six to eight months 350 ℔. At Vermont Station, in a 127 days' test, Chester Whites made an average gain of 1·36 ℔ and dressed 84·5 % carcase, and they can gain fully 1 ℔ of live weight for 3 ℔ of grain consumed.

Management.—The brood sow should be lengthy and of a prolific strain, known to milk well. She is moderately fed and put to a boar of her own age when large enough, *i.e.* seven to eight months old. She remains in a state of oestrum for about three days, and if not pregnant comes in heat again in three weeks. Breeding swine, male and female, run most of their time at pasture and receive a liberal allowance of green food or raw roots. The period of gestation is sixteen weeks. Six to eight pigs are reared of the first litter, and ten to twelve afterwards. Many brood sows are fattened to greatest profit after the second or third litter. Two litters are produced in one year, as pigs are usually weaned at two months old, and the sow will take the boar at from three days to a week after the pigs are removed, according to condition. A convenient sty to hold five or six pigs has a southern aspect, and consists of a covered compartment and outer court, each 10 ft. square. When the animals are fed outside the inner court is kept clean and dry, and there the pigs lie. The labouring man's pig is his bank, and is fed on scraps, small potatoes and waste products. In connexion with cheese dairies pigs are largely fed on sour whey thickened with mixed meal produced from any or all of the grains or pulses, the choice depending upon the market price. Food may with advantage be cooked for very young pigs; but, with the exception of potatoes, which should never be given raw, roots and meals are best given uncooked. Meal mixed with pulped roots for a few hours improves in digestibility, and a sprinkling of salt is an improvement. Meal derived from leguminous seeds makes the flesh firm and improves the quality. Fattening pigs are fed three times a day and supplied with coal-ashes or a few handfuls of earth. Of the fatted live weight of a pig 83 % is butcher's carcase, and 91 % of the increase from 100 to 200 ℔ is carcase. From 3 to 5 ℔ of meal consumed results in an increase of 1 ℔ of live weight in a pig, which is the most economical meat producer on a farm. Concentrated and digestible foods give best results, a pig has a small stomach. Fjord's Danish experiments show that for fattening pigs 1 ℔ of rye- or barley-meal is equivalent to 6 ℔ of skim-milk or 12 ℔ of whey, and 1 ℔ of meal equivalent to 8 ℔ of mangolds or 4 ℔ of potatoes.

PIGALLE, JEAN BAPTISTE (1714–1785), French sculptor, was born in Paris on the 26th of January 1714. He was the seventh child of a carpenter. Although he failed to obtain the *grand prix*, after a severe struggle he entered the Academy and became one of the most popular sculptors of his day. His earlier work, such as "Child with Cage" (model at Sèvres) and "Mercury Fastening his Sandals" (Berlin, and lead cast in Louvre), is less commonplace than that of his maturer years, but his nude statue of Voltaire, dated 1776 (Institut), and his tombs of Comte d'Harcourt (*c.* 1764) (Notre Dame) and of Marshal Saxe, completed in 1777 (Lutheran church, Strassburg), are good specimens of French sculpture in the 18th century. He died on the 28th of August 1785.

See P. Tarbé, *Vie et œuv. de Pigalle* (1859); Suard, *Éloge de Pigalle; Mélanges de littérature.*

PIGAULT-LEBRUN (Pigault de l'Epinoy), **CHARLES ANTOINE GUILLAUME** (1753–1835), French novelist, was born at Calais (he is said to have traced his pedigree on the mother's side to Eustache de St Pierre) on the 8th of April 1753. His youth was stormy. He twice carried off young ladies of some position, and was in consequence twice imprisoned by *lettre de cachet.* The first, a Miss Crawford, the daughter of an English merchant whose office Pigault had entered, died almost immediately after her elopement; the second, Mlle de Salens, he married. He became a soldier in the Queen's Guards, then a very unsuccessful actor, and a teacher of French. At the breaking out of the great war he re-enlisted and fought at Valmy. He wrote more than twenty plays, and a large number of novels, the first of which appeared in 1787. In his old age he took to graver work, and executed an abridgment of French history in eight volumes, besides some other work. His *Œuvres complètes* were published in twenty volumes between 1822 and 1824, but much of his work is subsequent to this collection. He died on the 24th of July 1835. The style of Pigault's novels is insignificant, and their morality very far from severe. As almost the father of a kind of literature which later developed enormously, Pigault-Lebrun deserves a certain place in literary history. Among the most celebrated of his novels may be mentioned *L'Enfant du Carnaval* (1792) and *Angélique et Jeanneton de la place Maubert* (1799). His *Citateur* (2 vols., 1803), a collection of quotations against Christianity, was forbidden and yet several times reprinted.

PIGEON (Fr. *pigeon*, Ital. *piccione* and *pipione*, Lat. *pipio*, literally a nestling-bird that pipes or cries out, a "piper"—the very name now in use among some pigeon-fanciers, though "squeaker" is the more usual term). The name pigeon, doubtless of Norman introduction as a polite term, seems to bear much the same relation to dove, the word of Anglo-Saxon origin, that mutton has to sheep, beef to ox, veal to calf, and pork to bacon; no sharp zoological distinction can be drawn (see Dove) between dove and pigeon, and the collective members of the group *Columbae* are by ornithologists ordinarily called pigeons. Perhaps the best-known species to which the latter name is exclusively given in common speech[1] is the wild pigeon

[1] It may be observed that the "rock-pigeons" of Anglo-Indians are Sand-grouse (*q.v.*), and the "Cape pigeon" of sailors is a petrel (*q.v.*).

in many cases, to select, or "pick over," the raw material, rejecting whatever impurities may weaken or injure the characteristic hue of the product.

Preparation.

It is occasionally necessary to treat the finely-ground substance with water by the method of elutriation or washing-over; the wash-waters will then deposit, on standing, various grades of the coloured body required. With rare exceptions native pigments need careful grinding, either by means of a muller on a slab or by edge rollers, or horizontal mill-stones, or special machines. The substance is usually ground in spirits of turpentine, or alcohol, or water; oil-paints are of course finally ground in a drying-oil, such as linseed oil or poppy oil; water-colours require gum-water, or gum-water and glycerin if they are to be "moist" paints. In the case of all pigments, whether mineral or organic, whether natural or artificial, it is of the highest importance to make sure that they are free from saline matters soluble in water. Such salts are removed by thorough washing with distilled water. A treatment of this kind is essential in the case of a large number of pigments formed by chemical reactions in the "wet way." Characteristic examples are furnished by Prussian blue, viridian and lakes. Sometimes it is necessary to remove dangerous impurities by solvents other than water, such as carbon bisulphide, which is used to extract free sulphur from cadmium yellow. Mention may here be made of another kind of preparative treatment which is adopted with some pigments: they are subjected to the action of heat—moderate in some cases, strong in others. Thus, a few substances, such as ivory black and yellow ochre, which in ordinary circumstances contain much non-essential moisture, before they are ground in oil may with advantage be gently dried at a temperature not above that of boiling water. Again, there are pigments, such as Prussian brown, light red and burnt sienna, which owe their hues to a process of actual calcination, the first of these being thus made from Prussian blue, the second from yellow ochre, and the third from raw sienna. The pigments known as burnt carmine and burnt madder are prepared at a much lower temperature, and ought to be described as roasted rather than as burnt.

The substitution of one pigment for another is rarely practised, but it is not so unusual to find that a costly substance has received an admixture of something cheaper, and that an inferior grade of a genuine pigment has had its hue exalted or enhanced by some unlawful or dangerous addition.

Adulteration.

In fact, these two kinds of sophistication are often associated. Thus vermilion is adulterated with red lead, with red antimony sulphide, or with baryta white and lead sulphate, and then the hue of the mixture is restored to the proper pitch by the introduction of the powerful but fugitive colouring matter eosin. Amongst other adulterations which may be named here are the addition of chrome-yellow (lead chromate) to yellow ochre, of green ultramarine to terre verte, and of indigo to ivory black; this last mixture being a substitute for vine-black, the natural blue-black. The detection of the above-named sophistications is by no means difficult even in the hands of persons unacquainted with chemical manipulation, but it needs a trained analyst when quantitative results are required. If we are dealing with an oil-colour, the first step is to remove the oil by means of a solvent, such, for example, as ether. The residual pigment is then allowed to dry, and the dry powder submitted to the appropriate physical and chemical tests. Thus a suspected vermilion, having been freed from oil, is heated in a small hard glass bulb-tube: it should prove practically volatile, leaving a mere trace of residue. In this particular case the presence of a red hue in the ether-extract affords evidence of adulteration with an organic colouring matter, such as eosin. Then, again, we may detect the presence in yellow ochre of lead chromate by pouring a little sulphuretted hydrogen water and dilute hydrochloric acid upon one portion of the dry pigment, and boiling another portion with dilute sulphuric acid and some alcohol: in the former experiment blackening will occur, in the latter the liquid part of the mixture will acquire a greenish tint. So also green ultramarine may be recognized in adulterated terre verte by the addition of dilute hydrochloric acid, which destroys the colour of the adulterant and causes an abundant evolution of the evil-smelling sulphuretted hydrogen. Moreover, nothing is easier than the recognition of indigo in vine or charcoal-black, for the dry powder, heated in a glass tube, gives off purple vapours of indigo, which condense in the cooler part of the tube into a blackish sublimate.

A word must be said here as to the adulteration of white lead, and the examination of this most important pigment. The best variety of white lead or flake white contains two molecules of lead carbonate to one of lead hydrate, and is wholly soluble in dilute nitric acid, while barium sulphate, its most frequent adulterant, is wholly insoluble. China-clay and lead sulphate will also remain undissolved; but whitening or chalk cannot be detected in this way—indeed, the thorough examination of white lead, not only for sophistications but also for correspondence with the best type in composition, cannot be carried out save by a skilled chemist.

Pigments may be classified on two systems: (1) based on the chemical composition; (2) based on the colour. On the first system pigments fall into nine groups, seven of which are fairly well defined, but the eighth and ninth have a somewhat miscellaneous character.

Classification.

The groups of elements, oxides, sulphides, hydrates, carbonates and silicates present this characteristic, namely, that each member of any one group is without action upon the other members of the group; any two or more may therefore be mixed together without fear of mutual injury. The same statement may be made with reference to the various inorganic salts of Group VIII. and to the organic compounds of Group IX., although in this large final group there are two pigments containing copper (verdigris and emerald green) which must be regarded with suspicion. The inertness of the members of the same group towards each other may be explained in the majority of cases by the following consideration. An oxide does not act upon an oxide, nor does a sulphide affect a sulphide, because all the pigment oxides have taken up their full complement of oxygen, and can neither give nor lose this element to similar oxides; so also with sulphur in the sulphides. A few details regarding the several members of the nine groups are now offered:—

GROUP I. *Elements.*—All the black pigments in ordinary use—ivory black, lamp black, charcoal black, Indian ink, and graphite, less correctly termed black-lead and plumbago—consist of or contain carbon, an element not liable to change. The metallic pigments, gold, silver, aluminium and platinum, belong here; of these, silver alone is easily susceptible of change, tarnishing by combination with sulphur.

GROUP II. *Oxides.*—The oxides have generally been formed at a high temperature and are not easily amenable to physical or chemical change; they are, moreover, not liable to affect other pigments, being practically inert, red lead only being an exception. The oxides include zinc white, green chromium oxide, burnt umber (a mixture of iron and manganese oxide), cobalt green ($CoO,nZnO$), cobalt blue (CoO,nAl_2O_3), coeruleum ($CoO,nSnO_2$), Venetian red, light red, Indian red and burnt sienna (all chiefly composed of ferric oxide), and red lead (Pb_3O_4).

GROUP III. *Sulphides.*—Some of the members of this group are liable to contain free sulphur, and some may give up this element to the metallic bases of other pigments. Thus cadmium yellow blackens emerald green, producing copper sulphide. Another pigment of this group, vermilion, is prone to a molecular change whereby the red form passes into the black variety. This change, frequent in water-colour drawings, is scarcely observable in works painted in oil. The sulphides comprise cadmium yellow (CdS), king's yellow (As_2S_3), realgar (As_2S_2), antimony red (Sb_2S_3) and vermilion (HgS). It is convenient to give places in the same group to the various kinds of ultramarine, blue, green, red, violet and native, for in all of them a part of the sulphur present occurs in the form of a sulphide. It may be stated that the sulphides of arsenic and antimony just named are dangerous and changeable pigments not suited for artistic painting.

GROUP IV. *Hydrates or Hydroxides.*—Several native earths belong here, notably yellow ochre, raw umber, raw sienna and Cappagh brown. These substances owe their colours mainly to hydrates and oxides of iron and of manganese, but the presence of a colourless body such as white clay or barium sulphate is usual with the paler pigments. A false yellow ochre from Cyprus is really a basic ferric sulphate, and does not properly belong to this

inbred, and is not so hardy and prolific as most breeds. The boars cross well with common stock. It merits the most credit in raising the quality of Irish pigs. In America it is in the front rank for numbers and quality as a lard-hog. There it often grows to be a larger and finer animal than it is in England.

The *Small Black* or *Black Suffolk* was produced from the old Essex pig by crossing with the Neapolitan. It resembles the Small White, except that the skin is coal-black in colour, and the coat of hair is not usually profuse. The Small Black, moreover, is rather longer, and stands somewhat higher, whilst it yields more lean meat than the Small White. It matures early and is quick to fatten.

The *Tamworth* is one of the oldest breeds of pigs. It is hardy, active and prolific, and nearly related to the wild boar. The colour is red or chestnut, with at times darkish spots on the skin. The head, body and legs are long, and the ribs deep and flat. Originally a local breed in the districts around the Staffordshire town from which it takes its name, it is now extensively bred, and highly valued as a bacon pig. (W. Fr.; R. W.)

In America nearly all the breeds may be classified as lard-hogs. Bacon-pigs fed on Indian corn degenerate into lard-hogs, run down in size and become too small in the bone and less prolific by inbreeding.

The *Poland-China*, the most popular breed in the United States, is thus degenerating. It is a black pig like the Berkshire, but has short lop-ears, a more pointed, straight nose, a more compact body, and more white markings. It is a breed of mixed blood, and is believed to have originated from the "Big China" pig—a large white hog with sandy spots, taken to Ohio in 1816, and blended with Irish graziers in 1839, and with a breed known as Bayfields, as well as with Berkshires. In Iowa the Berkshire is a combined lard and bacon pig in high favour.

The *Duroc Jersey* or *Duroc*, of a red or cherry-red colour—not sandy or dark—is the most popular pig in Nebraska and equal to any other in Iowa. It is a large prolific lard-hog, easily making 300 ℔ in eight months. It has gained rapidly in popularity since the beginning of this century, and is spreading to other centres.

The *Chester White*, named from Chester county, Pennsylvania, is one of the four leading breeds of lard-hogs in America. It is of mixed origin and bears a strong family resemblance to the Lincolnshire curly-coated pig. The early English ancestors, the breed of which is not on record in America, were most probably of Lincoln origin. The sow is a prolific breeder and good mother, weighing, when mature but not fat, 450 ℔—the boar averaging 600 ℔, and barrows at six to eight months 350 ℔. At Vermont Station, in a 127 days' test, Chester Whites made an average gain of 1·36 ℔ and dressed 84·5 % carcase, and they can gain fully 1 ℔ of live weight for 3 ℔ of grain consumed.

Management.—The brood sow should be lengthy and of a prolific strain, known to milk well. She is moderately fed and put to a boar of her own age when large enough, *i.e.* seven to eight months old. She remains in a state of oestrum for about three days, and if not pregnant comes in heat again in three weeks. Breeding swine, male and female, run most of their time at pasture and receive a liberal allowance of green food or raw roots. The period of gestation is sixteen weeks. Six to eight pigs are reared of the first litter, and ten to twelve afterwards. Many brood sows are fattened to greatest profit after the second or third litter. Two litters are produced in one year, as pigs are usually weaned at two months old, and the sow will take the boar at from three days to a week after the pigs are removed, according to condition. A convenient sty to hold five or six pigs has a southern aspect, and consists of a covered compartment and outer court, each 10 ft. square. When the animals are fed outside the inner court is kept clean and dry, and there the pigs lie. The labouring man's pig is his bank, and is fed on scraps, small potatoes and waste products. In connexion with cheese dairies pigs are largely fed on sour whey thickened with mixed meal produced from any or all of the grains or pulses, the choice depending upon the market price. Food may with advantage be cooked for very young pigs; but, with the exception of potatoes, which should never be given raw, roots and meals are best given uncooked. Meal mixed with pulped roots for a few hours improves in digestibility, and a sprinkling of salt is an improvement. Meal derived from leguminous seeds makes the flesh firm and improves the quality. Fattening pigs are fed three times a day and supplied with coal-ashes or a few handfuls of earth. Of the fatted live weight of a pig 83 % is butcher's carcase, and 91 % of the increase from 100 to 200 ℔ is carcase. From 3 to 5 ℔ of meal consumed results in an increase of 1 ℔ of live weight in a pig, which is the most economical meat producer on a farm. Concentrated and digestible foods give best results, a pig has a small stomach. Fjord's Danish experiments show that for fattening pigs 1 ℔ of rye- or barley-meal is equivalent to 6 ℔ of skim-milk or 12 ℔ of whey, and 1 ℔ of meal equivalent to 8 ℔ of mangolds or 4 ℔ of potatoes.

PIGALLE, JEAN BAPTISTE (1714–1785), French sculptor, was born in Paris on the 26th of January 1714. He was the seventh child of a carpenter. Although he failed to obtain the *grand prix*, after a severe struggle he entered the Academy and became one of the most popular sculptors of his day. His earlier work, such as "Child with Cage" (model at Sèvres) and "Mercury Fastening his Sandals" (Berlin, and lead cast in Louvre), is less commonplace than that of his maturer years, but his nude statue of Voltaire, dated 1776 (Institut), and his tombs of Comte d'Harcourt (*c.* 1764) (Notre Dame) and of Marshal Saxe, completed in 1777 (Lutheran church, Strassburg), are good specimens of French sculpture in the 18th century. He died on the 28th of August 1785.

See P. Tarbé, *Vie et œuv. de Pigalle* (1859); Suard, *Éloge de Pigalle: Mélanges de littérature.*

PIGAULT-LEBRUN (Pigault de l'Epinoy), **CHARLES ANTOINE GUILLAUME** (1753–1835), French novelist, was born at Calais (he is said to have traced his pedigree on the mother's side to Eustache de St Pierre) on the 8th of April 1753. His youth was stormy. He twice carried off young ladies of some position, and was in consequence twice imprisoned by *lettre de cachet*. The first, a Miss Crawford, the daughter of an English merchant whose office Pigault had entered, died almost immediately after her elopement; the second, Mlle de Salens, he married. He became a soldier in the Queen's Guards, then a very unsuccessful actor, and a teacher of French. At the breaking out of the great war he re-enlisted and fought at Valmy. He wrote more than twenty plays, and a large number of novels, the first of which appeared in 1787. In his old age he took to graver work, and executed an abridgment of French history in eight volumes, besides some other work. His *Œuvres complètes* were published in twenty volumes between 1822 and 1824, but much of his work is subsequent to this collection. He died on the 24th of July 1835. The style of Pigault's novels is insignificant, and their morality very far from severe. As almost the father of a kind of literature which later developed enormously, Pigault-Lebrun deserves a certain place in literary history. Among the most celebrated of his novels may be mentioned *L'Enfant du Carnaval* (1792) and *Angélique et Jeanneton de la place Maubert* (1799). His *Citateur* (2 vols., 1803), a collection of quotations against Christianity, was forbidden and yet several times reprinted.

PIGEON (Fr. *pigeon*, Ital. *piccione* and *pipione*, Lat. *pipio*, literally a nestling-bird that pipes or cries out, a "piper"—the very name now in use among some pigeon-fanciers, though "squeaker" is the more usual term). The name pigeon, doubtless of Norman introduction as a polite term, seems to bear much the same relation to dove, the word of Anglo-Saxon origin, that mutton has to sheep, beef to ox, veal to calf, and pork to bacon; no sharp zoological distinction can be drawn (see Dove) between dove and pigeon, and the collective members of the group *Columbae* are by ornithologists ordinarily called pigeons. Perhaps the best-known species to which the latter name is exclusively given in common speech[1] is the wild pigeon

[1] It may be observed that the "rock-pigeons" of Anglo-Indians are Sand-grouse (*q.v.*), and the "Cape pigeon" of sailors is a petrel (*q.v.*).

copper blues should be rejected. Prussian blue, or the mixture of this pigment with a white base which is usually called Antwerp blue, can scarcely be spared, but care should be taken to choose a sample containing no potassium compounds. Coeruleum, which may be described as cobalt stannate, presents the peculiarity of appearing a greenish blue in artificial light, not a purplish blue like that of ordinary cobalt blue. Cobalt violet is a sound pigment, while manganese metaphosphate or Nürnberg violet is said not to be safe in oil. Mars violet, an artificially prepared ferric oxide, is dull in hue but permanent. Passing on to brown pigments, it is matter for regret that there are no permanent colours possessing the artistic capacities of asphalt, madder brown, and the old bituminous Vandyke brown. Cappagh brown, burnt sienna, and raw and burnt umber may be employed safely. Little need be said as to the selection of black pigments, for all are permanent. The soot from burning acetylene, which has recently been introduced, forms a black pigment of remarkable intensity.

Uses.—Hitherto pigments have been considered chiefly in relation to the requirements of the painter of pictures. In many merely decorative arts, such as the manufacture of wall-papers and the painting of woodwork and of iron, the pigments available are in one direction, that of cost, more restricted, but, on the other hand, many alterable or weak pigments are commonly employed. In paints intended for the protection of iron-work, the nature of the pigment introduced is a matter of great moment, for red lead, zinc white and white lead are found to exert a strong protective influence, which is not observed in the case of the vast majority of pigments. There are a number of other uses besides those just named for which special pigments, or, more precisely, special paints, are employed. Amongst such preparations may be named luminous paints, anti-fouling paints, metallic paints, damp-proof paints, and asbestos and other fire-proof paints.

PIGOT, GEORGE, BARON (1719–1777), English governor of Madras, was born on the 4th of March 1719 and entered the service of the East India Company in 1736; after nineteen years he became governor and commander-in-chief of Madras in 1755. Having defended this place against the French in 1758–59 and occupied Pondicherry on behalf of the company, he resigned his office in November 1763 and returned to England, being made a baronet in 1764. In the following year he obtained a seat in parliament, and this he retained until his death; in 1766 he was created an Irish peer as Baron Pigot. Returning to India in 1775 to occupy his former position at Madras, Pigot was at once involved in a fierce quarrel with the majority of his council, which arose out of the proposed restoration of the rajah of Tanjore. The governor was arrested by order of his opponents, and was still a prisoner when he died on the 11th of May 1777. Meanwhile the conduct of Pigot was censured by the court of directors in England and the order for his restoration was followed immediately by another for his recall. This happened about a month after his death, but before the news had reached England. In 1779 the matter was discussed in parliament, and four of those who were responsible for his arrest were tried and were fined £1000 each. Pigot, who left several illegitimate children, was never married, and his barony became extinct.

Two of the governor's brothers were men of repute. SIR ROBERT PIGOT (1720–1796), who succeeded to the baronetcy, commanded his regiment (the 38th) at the battles of Lexington and Bunker Hill during the War of American Independence. He became a lieutenant-general in 1782. The other brother, HUGH PIGOT (*c.* 1721–1792), was a sailor. After some years of service he became an admiral and commander-in-chief in the West Indies in 1782. One of his sons was General SIR HENRY PIGOT (1750–1840), and another was HUGH PIGOT (1769–1797), a captain in the navy, who was murdered during a mutiny in September 1797 while in command of the "Hermione."

PIG-STICKING, or HOG-HUNTING, the chase of the wild boar, as a sport, on horseback with the spear. The chase on foot was common among ancient peoples, and in Central Europe has lasted to the present day, although, on account of the introduction of fire-arms, the spear has gradually become an auxiliary weapon, used to give the *coup de grâce* to a wounded animal. The modern sport is the direct descendant of bear-spearing which was popular in Bengal until the beginning of the 19th century, when the bears had become so scarce that wild pigs were substituted as the quarry. The weapon used by the Bengalese was a short, heavy, broad-bladed javelin. British officers introduced the spear or lance and this has become the recognized method of hunting wild pigs in India. The season for hunting in northern India, the present headquarters of the sport, is from February to July. The best horses should be quick and not too big. Two kinds of weapon are used. The long, or underhand, spear, weighing from two to three pounds, has a light, tough bamboo shaft, from seven to eight feet long, armed with a small steel head of varying shape. This spear is held in the hand about two-thirds the distance from the point, with the knuckles turned down and the thumb along the shaft. The short, or jobbing, spear is from six to six and a half feet long, and somewhat heavier than the longer weapon. It is grasped near the butt, with the thumb up. Although easier to handle in the jungle, it permits the nearer approach of the boar and is therefore more dangerous to man and mount.

Having arrived at the bush-grown or marshland haunt of the pigs, the quarry is "reared," *i.e.* chased out of its cover, by a long line of beaters, usually under the command of a mounted *shikari*. Sometimes dogs and guns loaded with small shot are used to induce an animal to break cover. The mounted sportsmen, placed on the edge of the cover, attack the pig as soon as it appears, the honour of "first spear," or "spear of honour," *i.e.* the thrust that first draws blood, being much coveted. As a startled or angry wild boar is a fast runner and a desperate fighter the pig-sticker must possess a good eye, a steady hand, a firm seat, a cool head and a courageous heart. For these reasons the military authorities encourage the sport, which is for the most part carried on by the tent clubs of the larger Indian stations.

The following technical terms are used. "Frank," a boar enclosure. "Jhow," the tamarisk, a common cover for boars. "Jink" (of the boar), to turn sharply to one side. "Nullah," a dry water-course. "To pig," to hunt the boar. "Pug," the boar's footprint. "Pugging," tracking the boar. "Ride to hog," to hunt the boar. "Rootings," marks of the pig's snout in the ground. "Sanglier" (or "singular"), a boar that has separated from the "sounder." "Sounder," a family of wild swine. "Squeaker," a pig under three years. "Tusker," a full-grown boar.

See *Pig-Sticking or Hog-Hunting*, by R. S. S. Baden-Powell (London, 1889).

PIKE, ZEBULON MONTGOMERY (1779–1813), American explorer and soldier, was born in Lamberton (now a part of Trenton), New Jersey, on the 5th of January 1779, son of Zebulon Pike (1751–1834), an officer in the American army. He entered his father's company as a cadet about 1794, and became an ensign (or second lieutenant) in 1799 and first lieutenant in the same year. On the 9th of August 1805 he started with twenty men from St Louis to explore the headwaters of the Mississippi. At Prairie du Chien he met some Chippewa chiefs and induced them to expel the whisky-traders among them and to make peace with the Sioux; at the Falls of St Anthony (Sept. 23) he bought a tract 9 m. square at the mouth of the St Croix for a fort; and at Little Falls (in the middle of October) he built a stockade, where he left seven men. He reached Leech Lake ("Lake La Sang Sue"), which he called "the main source of the Mississippi," on the 1st of February 1806; went 30 m. farther to Cass Lake ("Red Cedar"); and, after working against British influences among the Indians, turned back, and went down the Mississippi from Dean Creek to St Louis, arriving on the 30th of April. In 1806 he was

ordered to restore to their homes 50 Osages, redeemed by the United States government from Potawatami, and to explore the country. He started on the 15th of July; and went north along the Missouri and the Osage into the present state of Kansas and probably to the Republican River in the south of the present Nebraska, where on the 29th of September he held a grand council of the Pawnees. Then (early in October), turning nearly south, he marched to the Arkansas River, which he reached on the 14th of October, and up which (after the 28th with only 16 men) he went to the Royal Gorge (Dec. 7), having first seen the mountain called in his honour Pike's Peak on the 23rd of November; and then went north-west, probably up Oil Creek from Cañon City. In searching for the Red River he came to the South Platte, marched through South Park, left it by Trout Creek Pass, struck over to the Arkansas, which he thought was the Red River for which he was searching, and, going south and south-west, came to the Rio Grande del Norte (about where Alamosa, Conejos county, Colorado, is now) on the 30th of January 1807. There on the 26th of February he and a small number of his men were taken prisoners by Spanish authorities, who sent him first to Santa Fé, then to Chihuahua to General Salcedo, and by a roundabout way to the American frontier, where he was released on the 1st of July 1807. He was promoted captain (August 1806), major (May 1808), lieutenant-colonel (Dec. 1809) and colonel (July 1812). In 1808 he tried in vain to get an appropriation from Congress for himself and his men. He was military agent in New Orleans in 1809–1810, was deputy quartermaster-general in April–July 1812, and was in active service in the war of 1812 as adjutant and inspector-general in the campaign against York (now Toronto), Canada, and in the attack on York on the 27th of April 1813 was in immediate command of the troops in action and was killed by a piece of rock which fell on him when the British garrison in its retreat set fire to the magazine.

His *Account of an Expedition to the Sources of the Mississippi and through the Western Parts of Louisiana . . . and a Tour through the Interior Parts of New Spain* was published at Philadelphia in 1810; was reprinted and rearranged in London in 1811; and was published in a French version in Paris in 1812, and a Dutch version at Amsterdam in 1812–1813. The standard edition with memoir and notes by Elliott Coues was published in three volumes in New York in 1895. Some of Pike's papers taken from him in Mexico are now in the Mexican archives (Seccion de Asuntos Internacionales caxa 1817–1824), and the more important were published by H. E. Bolton in the *American Historical Review* (1907–1908), xiii. 798–827. See the sketch by Henry Whiting in series 2, vol. v., of Jared Sparks's *Library of American Biography.*

PIKE, fresh-water fishes generally distributed over the rivers and lakes of Europe, northern Asia, and North America, and forming a small family (*Esocidae*) of soft-rayed fishes. They are readily recognized by their elongate compressed body covered

European Pike (*Esox lucius*).

with small scales, a long head, long and spatulate snout, and very large mouth armed with strong and long teeth in the jaws and broad bands of smaller teeth on the palate and tongue. The teeth point backwards or can be depressed so as to offer no obstruction to any object entering the gape, but prevent its withdrawal in the opposite direction. The dorsal and anal fins are placed far back on the tail, thus greatly increasing the propelling power of the fish, and, although pike are bad swimmers and lead rather a sedentary than a roving life, they are excelled by no other fresh-water fish in rapidity of motion when, by a single stroke of the tail, they dash upon their prey or dart out of reach of danger. In the Old World one species only is known (*Esox lucius*), which prefers lakes and sluggish reaches of rivers to strong currents or agitated waters. Its eastward range in northern Asia is not known; it extends into Lapland in the north and into central Italy and the vicinity of Constantinople in the south, but is absent in the Iberian Peninsula. The European species occurs also in North America, and is common in the eastern United States southwards to northern Ohio. But North America is tenanted by other species of pike besides, of which the largest is the muskelunge or maskinonge of the Great Lakes (*Esox nobilior*); it commonly attains to the large size which is exceptionally recorded of *Esox lucius*. The other American pike are of smaller size, and generally named "pickerel"; but opinions as to the distinction of the species differ widely among American ichthyologists. The European pike, like its brethren, is the most voracious of fresh-water fishes; it probably exceeds the shark, to which it has been compared by many writers, in the relative quantity of food it consumes. Large specimens will seize rats or water-voles, and are said to attack even foxes and small dogs. Individuals of from 40 ℔ to 50 ℔ are not scarce, but captures of much larger ones are on record. Pike are wholesome food, and much esteemed in inland countries —the smaller (of 20 to 24 in. in length) being preferred to the larger individuals. They are prolific, and not easily exterminated in a water in which they have been once allowed to spawn. According to season and climate they spawn in April or May, and sometimes as early as February.

PIKE, a word which, with its collateral forms "pick" and "peak," has as its basic meaning that of anything pointed or tapering to a point. The ultimate etymology is much disputed, and the interrelation of the collaterals is very confused. In Old English there are two forms (*pic*), one with a long and the other with a short vowel, which give "pike" and "pick" respectively. The first form gave in the 15th century the variant "peak," first with reference to the peaked shoes then fashionable, *pekyd schone.* In Romanic languages are found Fr. *pic.*, Span. *pico*, Ital. *piccare*, to pierce, &c. There are also similar words in Welsh, Cornish and Breton. The Scandinavian forms, *e.g.* Swed. and Nor. *pik*, are probably taken from English. While some authorities take the Celtic as the original, others look to Latin for the source. Here the woodpecker, *pīcus*, is referred to, or more probably the root seen in *spica*, ear of corn, and *spina*, prickle (English spike, spine). The current differentiation in meanings attached to pike, pick and peak are more or less clearly marked, though in dialects they may vary. (1) *Pike*: Apart from the use as the name of the fish (see above), probably a shortened form of pike-fish, from its sharp, pointed beak, the common uses of the word are for a long hafted weapon with sharply pointed head of iron or steel, the common weapon of the foot-soldier till the introduction of the bayonet (see SPEAR and BAYONET), and for a hill with a pointed summit, appearing chiefly in the names of such hills in Cumberland, Westmorland and north-west Lancashire. It may be noticed that the proverbial expression "plain as a pike-staff" appears originally as "plain as a pack-staff," the flat plain sided staff on which a pedlar carried and rested his pack. The use of "pike" for a highway, a toll-gate, &c., is merely short for "turnpike." (2) *Pick*: As a substantive this form is chiefly used of the common tool of the navvy and the miner, consisting of a curved double-ended head set at right angles to the handle, one end being squared with a chisel edge, the other pointed, and used for loosening and breaking hard masses of earth, coal, &c. (see TOOLS). The other name for this tool, "pickaxe," is a corruption of the earlier *pikoys*, Fr. *picois*, M. Lat. *picosium*, formed from Fr. *pic*, the termination being adapted to the familiar English "axe." The sense-development of the verb "to pick" is not very clear, but the following meanings give the probable line: to dig into anything like a bird with its beak, in order to extract or remove something, to gather, pluck, hence to select, choose. (3) *Peak*: The chief uses are for the front of a cap or hat projecting sharply over the eyes, for the part of a ship's

hold where it narrows towards the bows, the fore-peak, or towards the stern, the after-peak, for the top corner of a sail extended by a gaff, or for the projecting end of the gaff itself, and for a pointed or conical top of a hill or mountain. The name of the high table-land district in Derbyshire is not to be connected with this word, but probably retains the name of an old English demon, *Peac* (see PEAK, THE).

PIKE-PERCH (*Lucioperca*), fresh-water fishes closely allied to the perch, but with strong canine teeth standing between the smaller teeth of the jaws and palate. They resemble the pike in their elongate body and head, and they are also most dangerous enemies to other fresh-water fishes, though they compensate for their destructiveness by the excellent flavour of their flesh. In Europe two species occur, the more celebrated being the "Zander" of North Germany or "Schiel" of the Danube (*Lucioperca sandra*); strange to say, it is absent in the system of the Rhine. It prefers the quiet waters of large rivers and clear deep lakes, in which it reaches a weight of 25 ℔ or 30 ℔. The second (*Lucioperca wolgensis*) is limited to rivers in southern Russia and Hungary. In North America several pike-perches have been described, but in the most recent works only two are distinguished, viz. *Lucioperca americana*, which grows to a weight of 20 ℔, and the much smaller *Lucioperca canadensis*; both are abundant in the Canadian lakes and upper Mississippi, and the latter also in the Ohio.

PIKE'S PEAK, a famous peak of the Rampart range of the Rocky Mountains in El Paso county, Colorado, U.S.A., about 6 m. W. of Colorado Springs. Though surpassed in altitude (14,108 ft.) by many summits in the state, no other is so well known. The commanding appearance of the peak is very fine. To the south are Cameron Cone (10,685 ft.), Mt Sachett, Mt Bald (13,974), Mt Rosa (11,427), and Mt Cheyenne (9407). From the summit the magnificent Sangre de Cristo range is in the foreground, while on a clear day not only its southernmost summit, Blanca Peak (14,390 ft.) is visible, but also the Spanish Peaks (12,708 and 13,623 ft.) 100 m. to the south, and Long's Peak 100 m. to the north, and between them Mt Lincoln, Gray's Peak and other giants. At the base of the mountain are Manitou and Colorado Springs, whence tourists can make the ascent of the peak (in summer safe and relatively simple) on horseback or by a cog-railway, 8·75 m. long (opened in 1891), which makes a total ascent of 8100 ft. (maximum gradient 1 in 4) to the summit. In 1905 a powerful searchlight was erected on the summit.

Pike's Peak was discovered in November 1806 by Lieut. Zebulon M. Pike. He attempted to scale it, but took the wrong path and found himself at the summit of Cheyenne Mountain. He pronounced the mountain unclimbable. In 1819 it was successfully climbed by the exploring party of Major S. H. Long.

PILASTER (Fr. *pilastre*, med. Lat. *pilastrum*, from *pila*, a pillar), in architecture, an engaged pier projecting slightly from the wall, and employed to divide up and decorate a wall surface or to serve as respond to a column. One of the earliest examples (*c.* 100 B.C.) exists in the propylaea at Priene in Asia Minor, where it tapers towards the top. Pilasters have bases and capitals and are frequently fluted like columns. The Romans would seem to have preferred semi-detached columns, but for their amphitheatres sometimes pilasters are employed, as in the upper story of the Colosseum. In the revival of Classic architecture, and especially in Italy, architects seem to have considered that no building was complete without a network of pilasters on every storey, and France and England followed their example; and not only externally but inside the great cathedrals and churches the pilaster is adopted as the simplest and best way of dividing the bays.

PILATE, PONTIUS, the Roman governor of Judaea under whom Jesus Christ suffered crucifixion. Of equestrian rank, his name Pontius suggests a Samnite origin, and his cognomen in the gospels, *pileatus* (if derived from the *pileus* or cap of liberty), descent from a freedman. In any case he came in A.D. 26 from the household of Tiberius, through the influence of Sejanus, to be procurator over part of the imperial province of Syria, viz. Judaea, Samaria and Idumea. He ruled ten years, quarrelled almost continuously with the Jews—whom Sejanus, diverging from the Caesar tradition, is said to have disliked—and in A.D. 36 was recalled. Before he arrived Tiberius died, and Pilate disappears from history. Eusebius relates (*Hist. eccl.* ii. 7)—but three centuries later and on the authority of earlier writers unnamed—that he was exiled to Gaul and committed suicide at Vienne.

Pilate kept the Roman peace in Palestine but with little understanding of the people. Sometimes he had to yield; as when he had sent the standards, by night, into the Holy City, and was besieged for five days by suppliants who had rushed to Caesarea (Jos. *Ant.* 31; *B. J.* ii. ix. 2, 3); and again when he hung up inscribed shields in Jerusalem, and was ordered by Tiberius to remove them to the other city (Philo *ad Gaium* 38). Sometimes he struck more promptly; as when the mob protested against his using the Temple treasure to build an aqueduct for Jerusalem, and he disguised his soldiers to disperse them with clubs (Jos. *Ant.* xviii. 3, 2); or when he "mingled the blood" of some unknown Galileans "with their sacrifices" (Luke xiii. 1); or slew the Samaritans who came to Mt Gerizim to dig up sacred vessels hidden by Moses there (Jos. *Ant.* xviii. 4, 1)—an incident which led to his recall. Philo, who tells how any suggestion of appeal by the Jews to Tiberius enraged him, sums up their view of Pilate in Agrippa's words, as a man "inflexible, merciless, obstinate."

A more discriminating light is thrown upon him by the New Testament narratives of the trial of Jesus. They illustrate the right of review or *recognitio* which the Romans retained, at least in capital causes; the charge brought in this case of acting *adversus majestatem populi romani*; the claim made by Jesus to be a king; and the result that his judge became convinced that the claimant was opposed neither to the public peace nor to the civil supremacy of Rome. The result is explained only by the dialogue, recorded exclusively in John, which shows the accused and the Roman meeting on the highest levels of the thought and conscience of the time. "I am come to bear witness unto the truth . . . Pilate answered, What is truth?" Estimates of Pilate's attitude at this point have varied infinitely, from Tertullian's, that he was "already in conviction a Christian"—*jam pro sua conscientia Christianus*—to Bacon's "jesting Pilate," who would not stay for a reply. We know only that to his persistent attempts thereafter to get his proposed verdict accepted by the people, came their fatal answer, "Thou art not Caesar's friend," and that at last he unwillingly ascended the *bema* (in this case a portable judgment-seat, brought for the day outside the Praetorium), and in such words as *Ibis ad crucem* "delivered Him to be crucified."

Pilate's place in the Christian tragedy, and perhaps also in the Creed, stimulated legend about him in two directions, equally unhistorical. The *Gospel of Nicodemus*, written by a Christian (possibly as early, Tischendorf thought, as the middle of the 2nd century), repeats the trial in a dull and diluted way; but adds not only alleged evidence of the Resurrection, but the splendid vision of the *descensus ad inferos*—the whole professing to be recorded in the *Acta Pilati* or official records of the governor. The *Epistola Pilati* gives Pilate's supposed account to Tiberius of the Resurrection; and the *Paradosis Pilati* relates how Tiberius condemned him and his wife Procla or Procula, both Christian converts. All this culminates in Pilate being canonized in the Abyssinian Church (June 25), and his wife in the Greek (Oct. 27). On the other hand the *Mors Pilati* tells how when condemned by the emperor he committed suicide; and his body, thrown first into the Tiber and then the Rhone, disturbed both waters, and was driven north into "Losania," where it was plunged in the gulf near Lucerne and below Mt Pilatus (originally no doubt *Pileatus* or cloud-capped), from whence it is raised every Good Friday to sit and wash unavailing hands.

BIBLIOGRAPHY.—For legends see Tischendorf's *Evangelia apocrypha* (1863) and *Apocryphal Gospels*, Ante-Nicene Lib. (1880).

The earlier Pilate literature, to the extent of 110 treatises, chiefly of the 17th and 18th centuries, is enumerated in G. A. Müller's *Pontius Pilatus der fünfte Prokurator von Judäa* (Stuttgart, 1888). See *in loco* in the following English or translated histories of the life or time of Jesus, Theodor Keim, E. Schürer, A. Edersheim, J. P. Lange, Bernhard Weiss and F. W. Farrar; *Expositor* (1884), p. 107 and (1900) p. 59; also H. Peter, "Pontius Pilatus, der römische Landpfleger in Judäa," in *Neue Jahrb. f. d. kl. Altertum* (1907). Sir James Fitzjames Stephen, in his *Liberty, Equality and Fraternity* (1873), p. 87, starts the question, "Was Pilate right in crucifying Christ": his somewhat paradoxical answer is criticised in *The Trial of Jesus Christ, a legal monograph*, by A. Taylor Innes (1899).
(A. T. I.)

PILATUS, LEO, or LEONTIUS [LEONZIO PILATO] (d. 1366), one of the earliest promoters of Greek studies in western Europe, was a native of Thessalonica. According to Petrarch, he was a Calabrian, who posed as a Greek in Italy and as an Italian abroad. In 1360 he went to Florence at the invitation of Boccaccio, by whose influence he was appointed to a lectureship in Greek at the Studio, the first appointment of the kind in the west. After three years he accompanied Boccaccio to Venice on a visit to Petrarch, whom he had already met at Padua. Petrarch, disgusted with his manners and habits, despatched him to Constantinople to purchase MSS. of classical authors. Pilatus soon tired of his mission and, although Petrarch refused to receive him again, set sail for Venice. Just outside the Adriatic Gulf he was struck dead by lightning. His chief importance lies in his connexion with Petrarch and Boccaccio. He made a bald and almost word for word translation of Homer into Latin prose for Boccaccio, subsequently sent to Petrarch, who owed his introduction to the poet to Pilatus and was anxious to obtain a complete translation. Pilatus also furnished Boccaccio with the material for his genealogy of the gods, in which he made an ostentatious display of Greek learning.

See Gibbon, *Decline and Fall*, ch. 66; G. Voigt, *Die Wiederbelebung des classischen Alterthums* (1893); H. Hody, *De Graecis illustribus* (1742); G. Tiraboschi, *Storia della letteratura italiana*, v. 691.

PILAU, a favourite Eastern dish, consisting essentially of rice, boiled with mutton or other meat, fowl or fish, and flavoured with spices, raisins, &c. The word appears in Persian, Turkish and Urdu, and has been adapted in European languages. The form *pilaff*, showing the Turkish pronunciation, is also common.

PILCHARD (in earlier 16th century forms *pylcher*, *pilchar*; of unknown origin; the Fr. *pilseir* is adapted from Eng.), *Clupea pilchardus*, a fish of the herring family (*Clupeidae*), abundant in the Mediterranean and on the Atlantic coasts of Europe, north to the English Channel. Sardine is another name for the same fish, which on the coast of Brittany and Normandy is also called *célan* or *céléren*. It is readily distinguished from the other European species of *Clupea*. The operculum is sculptured with ridges radiating and descending towards the suboperculum; the scales are large, about thirty along the lateral line, deciduous; the ventral fins are inserted below, or nearly below, the middle of the base of the dorsal fin; the dorsal fin has seventeen or eighteen, the anal from nineteen to twenty-one rays. A small blackish spot in the scapulary region is very constant, and sometimes succeeded by other similar marks. There are no teeth on the palate; pyloric appendages exist in great numbers; the vertebrae number fifty-three. The pilchard is one of the most important fishes of the English Channel. It spawns at a distance from the shore, and its eggs are buoyant, like those of many other marine fishes and unlike those of the herring, which are adhesive and demersal, *i.e.* develop under water. The egg of the pilchard is very easily distinguished from other pelagic eggs by the unusually large space separating the vitelline membrane from the contained ovum. Spawning takes place in summer, the season extending from June to October. When commencing their migrations towards the land the shoals consist of countless numbers, but they break up into smaller companies near the shore. Pilchards feed on minute crustaceans and other pelagic animals and require two or three years before they attain their full size, which is about 10 in. in length. The sardines of the west coast of France, which are tinned in oil for export, are immature fish of the same stock as those taken on the coasts of Cornwall; they are 5 to 7½ in. in length, and though such fish occur also on the Cornish coast it is only in small numbers and for brief periods. In the Mediterranean the sardine does not exceed 7¼ in. in length when mature. On the Pacific coast of America, in New Zealand and in Japan a pilchard occurs (*Clupea sagax*) which in its characters and habits is so similar to the European pilchard that its general utilization is deserving of attention. Immense shoals are reported to visit the east coast of Otago every year in February and March. *Clupea scombrina* is the "oil sardine" of the east coast of India.
(J. T. C.)

PILE, an homonymous word, of which the main branches are (1) a heap, through Fr. from *pila*, pillar; (2) a heavy beam used in making foundations, literally a pointed stake, an adaptation of Lat. *pilum*, javelin; (3) the nap on cloth, Lat. *pilus*, hair. In the first branch the Lat. *pila* (for *pigla*, from root of *pangere*, to fasten) meant also a pier or mole of stone, hence any mass of masonry, as in Fr. *pile*. In English usage the word chiefly means a "heap" or "mass" of objects laid one on the top of the other, such as the heap of faggots or other combustible material on which a dead body is cremated, "funeral pile," or on which a living person is burnt as a punishment. It also is applied to a large and lofty building, and specifically, to a stand of arms, "piled" in military fashion, and to the series of plates, "galvanic" or "voltaic piles," in an electric battery. The modern "head and tail" of a coin was formerly "cross and pile," Fr. *croix et pile*, in modern Fr. *face et pile*. In the older apparatus for minting the die for the reverse was placed on a small upright pillar, *pile*, the other on a puncheon known as a "trussell" (Fr. *trousseau*). The common name of the disease of haemorrhoids (*q.v.*) or "piles" is probably an extension of this word, in the sense of mass, swelling, but may be referred to the Lat. *pila*, ball. The name of the *pilum*, or heavy javelin (lit. pounder, pestle, from *pinsere*, *pisere*, to beat), the chief weapon of the ancient Roman infantry, was adopted into many Teutonic languages in the sense of dart or arrow, cf. Germ. *Pfeil*; in English it was chiefly used of a heavy stake with one end sharpened, and driven into swampy ground or in the bed of a river to form the first foundations for a building; the primitive lake-dwellings built on "piles" are also known as "pile-dwellings." For the use of piles in building see FOUNDATIONS and BRIDGES. In heraldry a charge represented by two lines meeting in the form of an arrow-head is known as a "pile," a direct adaptation probably of the Lat. *pilum*. The division of this intricate word, followed here, is that adopted by the *New English Dictionary*; other etymologists (*e.g.* Skeat, *Etym. Dict.*, 1898) arrange the words and their Latin originals somewhat differently.

PILGRIM, a wanderer, traveller, particularly to a holy place (see PILGRIMAGE). The earliest English forms are *pilegrim* or *pelegrim*, through Fr. *pèlerin* (the original O. Fr. *pelegrin* is not found), from Lat. *peregrinus*, a stranger, foreigner, particularly a resident alien in Rome (see PRAETOR and ROMAN LAW). The Lat. *pereger*, from which *peregrinus* is formed, meant "from abroad," "travelled through many lands" (*per*, through, and *ager*, country).

It was customary for pilgrims to bring back as proof of their pilgrimage to a particular shrine or holy place a badge, usually made of lead or pewter, bearing some figure or device identifying it with the name or place. These "pilgrim signs" are frequently alluded to in literature—notably in the *Canterbury Tales* and in *Piers Plowman*. The British Museum and the Musée Cluny in Paris have fine collections of them, mainly dredged from the Thames and the Seine. The badges were generally worn fastened to the pilgrim's hat or cape. Among the best known are those of the cockle or scallop shell of St James of Compostella in Spain; the "vernicle," a representation of the miraculous head of Christ; the *vera icon*, true image, on St Veronica's handkerchief, at Rome, or of the Abgar portrait at Genoa, cf. "a vernicle hadde he sowed on his cappe" (*Cant. Tales*, "Prol." 685); the Amiens badge of the head of John the Baptist on the charger, the cathedral claiming the custody of the relic from 1206 (fig. 1); and the palm branches or cross of palm leaf, the

hold where it narrows towards the bows, the fore-peak, or towards the stern, the after-peak, for the top corner of a sail extended by a gaff, or for the projecting end of the gaff itself, and for a pointed or conical top of a hill or mountain. The name of the high table-land district in Derbyshire is not to be connected with this word, but probably retains the name of an old English demon, *Peac* (see PEAK, THE).

PIKE-PERCH (*Lucioperca*), fresh-water fishes closely allied to the perch, but with strong canine teeth standing between the smaller teeth of the jaws and palate. They resemble the pike in their elongate body and head, and they are also most dangerous enemies to other fresh-water fishes, though they compensate for their destructiveness by the excellent flavour of their flesh. In Europe two species occur, the more celebrated being the "Zander" of North Germany or "Schiel" of the Danube (*Lucioperca sandra*); strange to say, it is absent in the system of the Rhine. It prefers the quiet waters of large rivers and clear deep lakes, in which it reaches a weight of 25 lb or 30 lb. The second (*Lucioperca wolgensis*) is limited to rivers in southern Russia and Hungary. In North America several pike-perches have been described, but in the most recent works only two are distinguished, viz. *Lucioperca americana*, which grows to a weight of 20 lb, and the much smaller *Lucioperca canadensis*; both are abundant in the Canadian lakes and upper Mississippi, and the latter also in the Ohio.

PIKE'S PEAK, a famous peak of the Rampart range of the Rocky Mountains in El Paso county, Colorado, U.S.A., about 6 m. W. of Colorado Springs. Though surpassed in altitude (14,108 ft.) by many summits in the state, no other is so well known. The commanding appearance of the peak is very fine. To the south are Cameron Cone (10,685 ft.), Mt Sachett, Mt Bald (13,974), Mt Rosa (11,427), and Mt Cheyenne (9407). From the summit the magnificent Sangre de Cristo range is in the foreground, while on a clear day not only its southernmost summit, Blanca Peak (14,390 ft.) is visible, but also the Spanish Peaks (12,708 and 13,623 ft.) 100 m. to the south, and Long's Peak 100 m. to the north, and between them Mt Lincoln, Gray's Peak and other giants. At the base of the mountain are Manitou and Colorado Springs, whence tourists can make the ascent of the peak (in summer safe and relatively simple) on horseback or by a cog-railway, 8·75 m. long (opened in 1891), which makes a total ascent of 8100 ft. (maximum gradient 1 in 4) to the summit. In 1905 a powerful searchlight was erected on the summit.

Pike's Peak was discovered in November 1806 by Lieut. Zebulon M. Pike. He attempted to scale it, but took the wrong path and found himself at the summit of Cheyenne Mountain. He pronounced the mountain unclimbable. In 1819 it was successfully climbed by the exploring party of Major S. H. Long.

PILASTER (Fr. *pilastre*, med. Lat. *pilastrum*, from *pila*, a pillar), in architecture, an engaged pier projecting slightly from the wall, and employed to divide up and decorate a wall surface or to serve as respond to a column. One of the earliest examples (*c.* 100 B.C.) exists in the propylaea at Priene in Asia Minor, where it tapers towards the top. Pilasters have bases and capitals and are frequently fluted like columns. The Romans would seem to have preferred semi-detached columns, but for their amphitheatres sometimes pilasters are employed, as in the upper story of the Colosseum. In the revival of Classic architecture, and especially in Italy, architects seem to have considered that no building was complete without a network of pilasters on every storey, and France and England followed their example; and not only externally but inside the great cathedrals and churches the pilaster is adopted as the simplest and best way of dividing the bays.

PILATE, PONTIUS, the Roman governor of Judaea under whom Jesus Christ suffered crucifixion. Of equestrian rank, his name Pontius suggests a Samnite origin, and his cognomen in the gospels, *pileatus* (if derived from the *pileus* or cap of liberty), descent from a freedman. In any case he came in A.D. 26 from the household of Tiberius, through the influence of Sejanus, to be procurator over part of the imperial province of Syria, viz. Judaea, Samaria and Idumea. He ruled ten years, quarrelled almost continuously with the Jews—whom Sejanus, diverging from the Caesar tradition, is said to have disliked—and in A.D. 36 was recalled. Before he arrived Tiberius died, and Pilate disappears from history. Eusebius relates (*Hist. eccl.* ii. 7)—but three centuries later and on the authority of earlier writers unnamed—that he was exiled to Gaul and committed suicide at Vienne.

Pilate kept the Roman peace in Palestine but with little understanding of the people. Sometimes he had to yield; as when he had sent the standards, by night, into the Holy City, and was besieged for five days by suppliants who had rushed to Caesarea (Jos. *Ant.* 31; *B. J.* ii. ix. 2, 3); and again when he hung up inscribed shields in Jerusalem, and was ordered by Tiberius to remove them to the other city (Philo *ad Gaium* 38). Sometimes he struck more promptly; as when the mob protested against his using the Temple treasure to build an aqueduct for Jerusalem, and he disguised his soldiers to disperse them with clubs (Jos. *Ant.* xviii. 3, 2); or when he "mingled the blood" of some unknown Galileans "with their sacrifices" (Luke xiii. 1); or slew the Samaritans who came to Mt Gerizim to dig up sacred vessels hidden by Moses there (Jos. *Ant.* xviii. 4, 1)—an incident which led to his recall. Philo, who tells how any suggestion of appeal by the Jews to Tiberius enraged him, sums up their view of Pilate in Agrippa's words, as a man "inflexible, merciless, obstinate."

A more discriminating light is thrown upon him by the New Testament narratives of the trial of Jesus. They illustrate the right of review or *recognitio* which the Romans retained, at least in capital causes; the charge brought in this case of acting *adversus majestatem populi romani*; the claim made by Jesus to be a king; and the result that his judge became convinced that the claimant was opposed neither to the public peace nor to the civil supremacy of Rome. The result is explained only by the dialogue, recorded exclusively in John, which shows the accused and the Roman meeting on the highest levels of the thought and conscience of the time. "I am come to bear witness unto the truth . . . Pilate answered, What is truth?" Estimates of Pilate's attitude at this point have varied infinitely, from Tertullian's, that he was "already in conviction a Christian"—*jam pro sua conscientia Christianus*—to Bacon's "jesting Pilate," who would not stay for a reply. We know only that to his persistent attempts thereafter to get his proposed verdict accepted by the people, came their fatal answer, "Thou art not Caesar's friend," and that at last he unwillingly ascended the *bema* (in this case a portable judgment-seat, brought for the day outside the Praetorium), and in such words as *Ibis ad crucem* "delivered Him to be crucified."

Pilate's place in the Christian tragedy, and perhaps also in the Creed, stimulated legend about him in two directions, equally unhistorical. The *Gospel of Nicodemus*, written by a Christian (possibly as early, Tischendorf thought, as the middle of the 2nd century), repeats the trial in a dull and diluted way; but adds not only alleged evidence of the Resurrection, but the splendid vision of the *descensus ad inferos*—the whole professing to be recorded in the *Acta Pilati* or official records of the governor. The *Epistola Pilati* gives Pilate's supposed account to Tiberius of the Resurrection; and the *Paradosis Pilati* relates how Tiberius condemned him and his wife Procla or Procula, both Christian converts. All this culminates in Pilate being canonized in the Abyssinian Church (June 25), and his wife in the Greek (Oct. 27). On the other hand the *Mors Pilati* tells how when condemned by the emperor he committed suicide; and his body, thrown first into the Tiber and then the Rhone, disturbed both waters, and was driven north into "Losania," where it was plunged in the gulf near Lucerne and below Mt Pilatus (originally no doubt *Pileatus* or cloud-capped), from whence it is raised every Good Friday to sit and wash unavailing hands.

BIBLIOGRAPHY.—For legends see Tischendorf's *Evangelia apocrypha* (1863) and *Apocryphal Gospels*, Ante-Nicene Lib. (1880).

gave rise to all manner of religious expeditions. Even among the Israelites, the visitation of certain cult-centres prevailed from remote antiquity; but, when the restriction of Yahweh-worship to Jerusalem had doomed the old shrines, the Jewish pilgrimages were directed solely to the sanctuary on Mt Moria.

Among the Greeks the habit was no less deeply rooted. Just as the inhabitants of each town honoured their tutelar deity by solemn processions to his temple, so, at the period of the Olympic games, the temple of Zeus at Olympia formed the goal of multitudes from every Hellenic country. No less powerful was the attraction exercised by the shrines of the oracular divinities, though the influx of pilgrims was not limited to certain days, but, year in and year out, a stream of private persons, or embassies from the city-states, came flowing to the temple of Zeus in Dodona or the shrine of Apollo at Delphi.

The unification of the peoples of antiquity in the Roman Empire, and the resultant amalgam of religions, gave a powerful impetus to the custom. For, as East and West still met at the old sanctuaries of Greece, so—and yet more—Greece and Rome repaired to the temples of the southern and eastern deities. In the shrine of Isis at Philae, Europeans set up votive inscriptions on behalf of their kindred far away at home, and it may be surmised that even among the festival crowds at Jerusalem a few Greeks found place (John xii. 20).

The pilgrimage, however, attained its zenith under Islam. For Mahomet proclaimed it the duty of every Mussulman, once at least in his life, to visit Mecca; the result being that the birthplace of the Prophet is now the religious centre of the whole Mahommedan world (see MAHOMMEDAN RELIGION; CARAVAN; MECCA).

II. *The Pilgrimage under Christianity.*—The pilgrimages of Christianity presuppose the existence of those of paganism; but it would be an error to maintain that the former were a direct development of the latter. For primitive Christianity was devoid of any point by which these journeys of devotion might naturally have been suggested. It was a religion without temples, without sanctuaries, and without ceremonial. The saying of the Johannine Gospel—that God is to be adored neither in Jerusalem nor on Gerizim, but that His true worshipper must worship Him in spirit and in truth—is in complete harmony with the old Christian piety. And, accordingly, in the ancient Christian literature, we find no trace of a conception that the believer should visit a definite place in order to pay homage to his Master. The evolution of the Christian pilgrimage moved on other lines.

Origin.

Cicero finely observes that, in Athens, the glorious architecture caused him less pleasure than did the thought of the great men whose work was done in its midst—"how here one had lived, and there fallen asleep; how here another had disputed, and there lay buried" (*De Legg.* ii. 2). This feeling was not weakened by the advent of Christianity, in fact, we may say that it was appreciably strengthened. Cicero had already compared the sites consecrated by the memory of some illustrious name with those hallowed by recollections of a loved one. But with the Christian, when his Redeemer was in question, both motives coincided: for there the greatest was also the dearest.

In this devotion to the memory of Jesus, we find the key to the origin of the Christian pilgrimage: the faithful repaired to those places which were invested with memories of their Lord's earthly life. And these journeys must certainly date from the 2nd century. For Origen (d. 254) mentions that in Bethlehem the cave was shown where Christ was born, and in it the manger in which Mary made the bed of her child. The site must have been much visited long before this, since Origen remarks that it was common knowledge, even among the infidels, that there was the birthplace of that Jesus whom the Christians worshipped (*Contr. Cels.* i. 51). But those who visited Bethlehem must certainly have visited Jerusalem and the places there, so rich in memorials of their Master. And the sympathy of Christendom soon led them beyond this immediate circle. The anonymous author of the *Cohortatio ad Graecos*, a work of the 2nd century, visited the remnants of those cells, in which—so legend related—the seventy interpreters laboured on their version of the Old Testament: nor, when he came to Cumae in Campania, did he fail to have shown him the old shrine of the Sibyl (*Coh. ad Gr.* 13 and 37). Soon we begin to hear the names of the pilgrims. In the course of the 3rd century, as Jerome relates, Firmilian, bishop of Caesarea in Cappadocia, travelled to Palestine to view the sacred places (*De Vir. ill.* 54): while, according to Eusebius, a second bishop from Cappadocia, Alexander by name, visited Jerusalem in order to pray and acquaint himself with the holy sites, and was there invited by the community to remain with them and assume the episcopate of the aged Narcissus (*Hist. eccl.* vi. 11). With regard to his own times—the early years of the 4th century—the same authority recounts that believers kept streaming to Palestine from all regions, there to offer their prayers at a cavern shown on the Mount of Olives (*Demonstr. evang.* vi. 18).

This statement, that the Christians of the 3rd and 4th centuries were in the habit of visiting Jerusalem for prayer, proves that the non-Christian conception of the religious pilgrimage had already entered the sphere of Christian thought. That men travelled for purposes of prayer implies acceptance of the heathen theory of sanctuaries which it is an act of piety to visit. We may regret the fact, for it sullied the purity of primitive Christian thought. Nevertheless, it is clear that the development was inevitable. As soon as the non-Christian ideas of priests, sacrifices, houses of the god, and so forth, were naturalized in the Christianity of the 3rd century, it was but a short step to the belief in holy places.

III. *The Pilgrimage in the Ancient Church.*—In the passages cited above, Bethlehem and the Mount of Olives figure as the main goal of the pilgrim; and on the Mount of Olives the mind must naturally turn to the Garden of Gethsemane and the scene of the Ascension. It may seem surprising that there is no mention of Golgotha and the Sepulchre. But the visitation of these sites was rendered impossible to the Christians by the destruction of Jerusalem and the erection of the town of Aelia Capitolina. They had not forgotten them; but the grave was concealed under a mound of earth and stones—a profanation probably dating from the siege of the city and Titus's attack on the second wall. On the summit of this mound there stood, in the days of Eusebius, a sanctuary of Venus (Eus. *Vit. Const.* iii. 26, 30). The Sepulchre and the Hill of the Crucifixion were lost to the Christian pilgrim; and, consequently, before the era of Constantine, the one holy site in the town of Jerusalem was the so-called *Coenaculum*, which received its name in later years. It lay south of the city, near the outer wall, and, if Epiphanius is to be believed, was already in existence when Hadrian (130–131) visited Jerusalem (*De mens.* 14). It was regarded as the house, in which—according to the Acts of the Apostles (xii. 12 sqq.)—Mary, the mother of John Mark, lived; and the belief was that there the Lord held the Last Supper, and that there the eleven assembled after the Ascension. It was there, also, that the scene of the Pentecostal effusion of the Spirit was laid (cf. Cyrill. *Hierus. Cat.* xvi. 4).

The East.

The pilgrimage to Palestine received a powerful impetus from the erection of the memorial churches on the holy sites, under Constantine the Great, as described by Eusebius in his biography of the emperor (iii. 25 sqq.). At the order of Constantine, the shrine of Venus above mentioned was destroyed, and the accumulated rubbish removed, till the ancient rock-foundation was reached. There the cave was discovered in which Joseph of Arimathea had laid the body of Jesus; and above this cave and the Hill of the Crucifixion the imposing church of the Holy Sepulchre was built (A.D. 326–336). The churches in Bethlehem and on the Mount of Olives were erected by Helena, the mother of Constantine, who herself undertook the pilgrimage to the Holy Land. These churches were then endowed with new sanctuaries of miraculous powers; and relics of Christ were found in the shape of the Cross and the nails. Eusebius, the contemporary of Constantine, is silent on this point. To his continuators, on the other hand, it is an established fact that Helena brought all three crosses to light, and ascertained

the genuine Cross by the instrumentality of a miracle, in addition to discovering the nails of the Crucifixion (Rufin. i. 7; Socr. i. 17; Sozomen. ii. 1; Theod. i. 17). It is impossible to fix the date at which the supposititious relics were introduced into the church of the Sepulchre: it is certain, however, that in the 5th century the Cross was there preserved with scrupulous reverence, and accounted the highest treasure of the sanctuary.

After the 4th century, monks and nuns begin to form no inconsiderable part of the pilgrimages—a fact which is especially manifest from the numerous notices to be found in Jerome, and the narratives of Theodoret in the *Historia religiosa*. In fact, many were inclined to regard a journey to Jerusalem as the bounden duty of every monk—an exaggerated view which led to energetic protests, especially from Gregory of Nyssa, who composed a monograph on the pilgrimages *De iis qui adeunt Hierosol.*). Jerome, like Gregory, insists on the point that residence in Jerusalem has in itself no religious value: it is not locality, but character, that avails, and the gates of Heaven are as open in Britain as in Jerusalem (*Ep.* 58, 3). These utterances, however, must not be misinterpreted. They are not directed against the pilgrimage in itself, nor even against the belief that prayer possesses special efficacy on sacred ground, but solely against the exaggerated developments of the system.

The theologians of the 4th and 5th centuries were at one with the masses in recognizing the religious uses of the pilgrimages. Jerome in particular considered it an act of faith for a man to offer his prayers where the feet of the Lord had stood, and the traces of the Birth, of the Cross, and of the Passion were still to be seen (*Ep.* 47, 2).

We may gain some impression of the mood in which the pilgrims completed their journey, when we read how Paula, the friend of Jerome, expresses herself on her visit to the church of the Sepulchre: "As oft as we enter its precincts we see the Saviour laid in the shroud, and the angel seated at the feet of the dead!" (Hieron. *Ep.* 46, 2). She assured Jerome that, in the church of the Nativity at Bethlehem, she beheld, with the eye of faith, the Christ-child wrapped in swaddling clothes (*Ep.* 108, 10). But with these thoughts, others of an entirely different stamp were frequently blended. Pilgrimages were conceived as means to ensure an answer to particular prayers. So, for example, Eudocia, the wife of Theodosius II., vowed to undertake a pilgrimage to Jerusalem, if she should see her daughter married (Socr. *Hist. eccl.* vii. 47). And, closely as this approaches to pagan ideas, the distinction between paganism and Christianity is completely obliterated when we find the hermit Julian and his companions travelling to Sinai in order to worship the Deity there resident (Theod. *Hist. rel.* 2).

With the number of the pilgrims the number of pilgrim-resorts also increased. Of Jerusalem alone Jerome relates that the places of prayer were so numerous that it was impossible to visit them all in one day (*Ep.* 46, 9). In the Holy Land the list was still longer: the natives were ready to show everything for which the foreigners inquired, and the pilgrim was eager to credit everything. In her expedition to the East, the Paula mentioned above visited, among other places, Sarepta and Caesarea. In the first-named place she was shown the tower of Elijah; in the second, the house of Cornelius, that of Philip, and finally the grave of the four virgins. At Bethlehem she saw, in addition to the church of the Nativity, the grave of Rachel; at Hebron the hut of Sarah, in which the swaddling clothes of Isaac and the remains of Abraham's oak were on view (Hieron. *Ep.* 108). A similar picture is given in the *Travels* of the so-called Silvia Aquitana, who seems, in reality, to have been a Spanish nun, named Etheria or Eucheria. She went as a pilgrim to Jerusalem (*c.* 380), and from there traversed the whole of Palestine, in order to visit every site which was consecrated by memories of the Lord's earthly life. Nor did she neglect the scenes of partriarchal history. Of greater antiquity is the concise account of his travels by an anonymous pilgrim, who, in A.D. 333, undertook the journey from Bordeaux to Palestine. The *Itinerary* of the African Theodosius who visited the East between A.D. 520 and A.D. 530 is of later date (P. Geyer, *Itin. hierosol. saec.* iv.–viii.).

In the West.

While pilgrim-resorts were thus filling the East, their counterparts began to emerge in the West. And here the starting-point is to be found in the veneration of martyrs. Care for the tombs of martyrs was sanctioned by immemorial custom of the Church; but, in this case also, a later age failed to preserve the primitive conception in its purity; and Augustine himself was obliged to defend the usage of the Church from the imputation that it implied a transference of heathen ceremonial to the sphere of Christianity (*Contr. Faust.* xx. 21). The martyrs were the local heroes of particular communities; but there were men whose life and death were of significance for the whole of Christendom—the apostles. Of these Peter and Paul had suffered martyrdom in Rome, and it was inevitable, from the nature of the case, that their graves should soon become a resort, not only of Romans born, but of strangers also. True, the presbyter Caius (*c.* 200) who first mentions the situation of the apostolic tombs on the Vatican and the road to Ostia, and refers to the memorials there erected, has nothing to say of foreign Christians journeying to Rome in order to visit them. And though Origen travelled to Rome, it was not to view the graves of dead men, but to establish relations with the living flock (Euseb. *Hist. eccl.* ii. 25, 7; vi. 14, 10); still, it is certain that the Roman cemeteries were visited by numerous pilgrims even in the 3rd century: for the earliest *graffiti* in the papal crypt of the Coemeterium Callisti must date from this period (De Rossi, *Roma sotter.* i. 253 sqq.; Kraus, *Rom. Sott.* 148 sqq.). And if the tombs of the popes were thus visited, so much more must this hold of the tombs of the apostles. After these, the most frequented resort at Rome in the 4th century was the grave of Hippolytus. The poet Prudentius describes how, on the day of the martyr's death, an innumerable multitude of pilgrims flocked round the site. Even on ordinary days arrivals and departures were almost incessant—foreigners being everywhere seen mingled with the native Latins. They poured balsam on the sepulchre of the saint, washed it with their tears, and covered it with their kisses, in the belief that they were thus assuring themselves of his intercession or testifying their gratitude for his assistance. Prudentius says of himself, that whenever he was sick in soul or body, and prayed there, he found help and returned in cheerfulness: for God had vouchsafed His saint to the power answer all entreaties (*Perist.* xi. 175 sqq.). Paulinus of Nola (d. 431) concurs—his custom being to visit Ostia each year, and Rome on the apostolic anniversaries (*Ep.* 20, 2; 45, 1). Next to Rome the most popular religious resort was the tomb of Felix of Nola (August. *Ep.* 78, 3); while in Gaul the grave of St Martin at Tours drew pilgrims from all quarters (Paul. Nol. *Ep.* 17, 4). Africa possessed no sanctuary to compete with these; but we learn from Sulpicius Severus (*c.* 400) that the tomb of Cyprian seems to have been visited even by a Gaul (*Dial.* i. 3).

The motive that drew the pilgrims to the graves of the saints is to be found in the conviction, expressed by Prudentius, that there divine succour was certain; and hence came the belief in a never-ending series of miracles there performed (cf. *e.g.* Ennod. Ticin. *Lib. pro syn.* p. 315). Doubt was unknown. St Augustine observes that, though Africa was full of martyrs' tombs, no miracle had been wrought at them so far as his knowledge extended. This, however, did not lead him to doubt the truth of those reported by others—a fact that is somewhat surprising when we reflect that the phenomenon caused him much disquiet and perplexity. Who, he asks, can fathom the design of God in ordaining that this should happen at one place and not at another? And eventually he acquiesces in the conclusion that God, who gives every man his individual gift at pleasure, has not willed that the same powers should have efficacy at every sepulchre of the saints (*Ep.* 78, 3).

IV. *The Pilgrimage in the Middle Ages.*—The medieval Church

gave rise to all manner of religious expeditions. Even among the Israelites, the visitation of certain cult-centres prevailed from remote antiquity; but, when the restriction of Yahweh-worship to Jerusalem had doomed the old shrines, the Jewish pilgrimages were directed solely to the sanctuary on Mt Moria.

Among the Greeks the habit was no less deeply rooted. Just as the inhabitants of each town honoured their tutelar deity by solemn processions to his temple, so, at the period of the Olympic games, the temple of Zeus at Olympia formed the goal of multitudes from every Hellenic country. No less powerful was the attraction exercised by the shrines of the oracular divinities, though the influx of pilgrims was not limited to certain days, but, year in and year out, a stream of private persons, or embassies from the city-states, came flowing to the temple of Zeus in Dodona or the shrine of Apollo at Delphi.

The unification of the peoples of antiquity in the Roman Empire, and the resultant amalgam of religions, gave a powerful impetus to the custom. For, as East and West still met at the old sanctuaries of Greece, so—and yet more—Greece and Rome repaired to the temples of the southern and eastern deities. In the shrine of Isis at Philae, Europeans set up votive inscriptions on behalf of their kindred far away at home, and it may be surmised that even among the festival crowds at Jerusalem a few Greeks found place (John xii. 20).

The pilgrimage, however, attained its zenith under Islam. For Mahomet proclaimed it the duty of every Mussulman, once at least in his life, to visit Mecca; the result being that the birthplace of the Prophet is now the religious centre of the whole Mahommedan world (see MAHOMMEDAN RELIGION; CARAVAN; MECCA).

II. *The Pilgrimage under Christianity.*—The pilgrimages of Christianity presuppose the existence of those of paganism; but it would be an error to maintain that the former were a direct development of the latter. For primitive Christianity was devoid of any point by which these journeys of devotion might naturally have been suggested. It was a religion without temples, without sanctuaries, and without ceremonial. The saying of the Johannine Gospel—that God is to be adored neither in Jerusalem nor on Gerizim, but that His true worshipper must worship Him in spirit and in truth—is in complete harmony with the old Christian piety. And, accordingly, in the ancient Christian literature, we find no trace of a conception that the believer should visit a definite place in order to pay homage to his Master. The evolution of the Christian pilgrimage moved on other lines.

Origin.

Cicero finely observes that, in Athens, the glorious architecture caused him less pleasure than did the thought of the great men whose work was done in its midst—"how here one had lived, and there fallen asleep; how here another had disputed, and there lay buried" (*De Legg.* ii. 2). This feeling was not weakened by the advent of Christianity, in fact, we may say that it was appreciably strengthened. Cicero had already compared the sites consecrated by the memory of some illustrious name with those hallowed by recollections of a loved one. But with the Christian, when his Redeemer was in question, both motives coincided: for there the greatest was also the dearest.

In this devotion to the memory of Jesus, we find the key to the origin of the Christian pilgrimage: the faithful repaired to those places which were invested with memories of their Lord's earthly life. And these journeys must certainly date from the 2nd century. For Origen (d. 254) mentions that in Bethlehem the cave was shown where Christ was born, and in it the manger in which Mary made the bed of her child. The site must have been much visited long before this, since Origen remarks that it was common knowledge, even among the infidels, that there was the birthplace of that Jesus whom the Christians worshipped (*Contr. Cels.* i. 51). But those who visited Bethlehem must certainly have visited Jerusalem and the places there, so rich in memorials of their Master. And the sympathy of Christendom soon led them beyond this immediate circle. The anonymous author of the *Cohortatio ad Graecos*, a work of the 2nd century, visited the remnants of those cells, in which—so legend related—the seventy interpreters laboured on their version of the Old Testament: nor, when he came to Cumae in Campania, did he fail to have shown him the old shrine of the Sibyl (*Coh. ad Gr.* 13 and 37). Soon we begin to hear the names of the pilgrims. In the course of the 3rd century, as Jerome relates, Firmilian, bishop of Caesarea in Cappadocia, travelled to Palestine to view the sacred places (*De Vir. ill.* 54): while, according to Eusebius, a second bishop from Cappadocia, Alexander by name, visited Jerusalem in order to pray and acquaint himself with the holy sites, and was there invited by the community to remain with them and assume the episcopate of the aged Narcissus (*Hist. eccl.* vi. 11). With regard to his own times—the early years of the 4th century—the same authority recounts that believers kept streaming to Palestine from all regions, there to offer their prayers at a cavern shown on the Mount of Olives (*Demonstr. evang.* vi. 18).

This statement, that the Christians of the 3rd and 4th centuries were in the habit of visiting Jerusalem for prayer, proves that the non-Christian conception of the religious pilgrimage had already entered the sphere of Christian thought. That men travelled for purposes of prayer implies acceptance of the heathen theory of sanctuaries which it is an act of piety to visit. We may regret the fact, for it sullied the purity of primitive Christian thought. Nevertheless, it is clear that the development was inevitable. As soon as the non-Christian ideas of priests, sacrifices, houses of the god, and so forth, were naturalized in the Christianity of the 3rd century, it was but a short step to the belief in holy places.

III. *The Pilgrimage in the Ancient Church.*—In the passages cited above, Bethlehem and the Mount of Olives figure as the main goal of the pilgrim; and on the Mount of Olives the mind must naturally turn to the Garden of Gethsemane and the scene of the Ascension. It may seem surprising that there is no mention of Golgotha and the Sepulchre. But the visitation of these sites was rendered impossible to the Christians by the destruction of Jerusalem and the erection of the town of Aelia Capitolina. They had not forgotten them; but the grave was concealed under a mound of earth and stones—a profanation probably dating from the siege of the city and Titus's attack on the second wall. On the summit of this mound there stood, in the days of Eusebius, a sanctuary of Venus (Eus. *Vit. Const.* iii. 26, 30). The Sepulchre and the Hill of the Crucifixion were lost to the Christian pilgrim; and, consequently, before the era of Constantine, the one holy site in the town of Jerusalem was the so-called *Coenaculum*, which received its name in later years. It lay south of the city, near the outer wall, and, if Epiphanius is to be believed, was already in existence when Hadrian (130–131) visited Jerusalem (*De mens.* 14). It was regarded as the house, in which—according to the Acts of the Apostles (xii. 12 sqq.)—Mary, the mother of John Mark, lived; and the belief was that there the Lord held the Last Supper, and that there the eleven assembled after the Ascension. It was there, also, that the scene of the Pentecostal effusion of the Spirit was laid (cf. Cyrill. *Hierus. Cat.* xvi. 4).

The East.

The pilgrimage to Palestine received a powerful impetus from the erection of the memorial churches on the holy sites, under Constantine the Great, as described by Eusebius in his biography of the emperor (iii. 25 sqq.). At the order of Constantine, the shrine of Venus above mentioned was destroyed, and the accumulated rubbish removed, till the ancient rock-foundation was reached. There the cave was discovered in which Joseph of Arimathea had laid the body of Jesus; and above this cave and the Hill of the Crucifixion the imposing church of the Holy Sepulchre was built (A.D. 326–336). The churches in Bethlehem and on the Mount of Olives were erected by Helena, the mother of Constantine, who herself undertook the pilgrimage to the Holy Land. These churches were then endowed with new sanctuaries of miraculous powers; and relics of Christ were found in the shape of the Cross and the nails. Eusebius, the contemporary of Constantine, is silent on this point. To his continuators, on the other hand, it is an established fact that Helena brought all three crosses to light, and ascertained

every religious resort; in Lucca the father died, and the brother remained behind in Rome. Early in 722 Willibald began his expedition to the Holy Land alone, except for the presence of two companions. He travelled past Naples to Syracuse, then on shipboard by Cos and Samos to Ephesus, and thence through Asia Minor to Damascus and Jerusalem. On St Martin's day, in 724, he arrived in the Holy City. After a prolonged stay in the town and its environs, Willibald proceeded (727) to Constantinople, and in 729 returned to Italy. Such is the account given by the nun of Heidenheim in her biography of Willibald; and her version is probably based on notes by the pilgrim himself (*Mon. Germ. hist. scr.* xv. 80 sqq.). In the 9th century the French monk Bernard visited Palestine with two companions, and afterwards wrote a simple and trustworthy account of his journey (*Patrol. lat.* 121, 569 sqq.). In the 10th century Conrad, bishop of Constance (934–976), performed the pilgrimage to Jerusalem three times (*Vita Chuonr.* 7); and to the same period belong the first women-pilgrims to Jerusalem of whom we have any cognisance—Hidda, mother of Gero, archbishop of Cologne (Thietm. *Chron.* ii. 16), and the countess Hademod of Ebersberg (*Chron. ebersb.*). The leaders, moreover, of the monkish reform movement in the 10th and 11th centuries, Richard of St Vanne in Verdun and Poppo, abbot of Stavelot (978–1048), had seen the Holy Land with their own eyes (*Vita Rich.* 17; *Vita Popp.* 3). In the year 1028 Archbishop Poppo of Trier (d. 1047) undertook a pilgrimage which led him past Jerusalem to the banks of the Euphrates, his return taking place in 1030 (*Gesta Trevir. Cont.* i. 4 seq.). But the most celebrated devotional expedition before the Crusades was that of the four bishops—Sigfrid of Mainz, Gunther of Bamberg, William of Utrecht, and Otto of Regensburg. They set out in 1064, with a company whose numbers exceeded seven thousand. The major portion, however, fell in battle against the Mahommedans, or succumbed to the privations of the journey, and only some two thousand saw their homes again (*Annal. Altah., Lamb., Disib., Marian. Scot.* &c.). Among the followers of the bishops were two clerics of Bamberg, Ezzo and Wille, who composed on the way the beautiful song on the miracles of Christ—one of the oldest hymns in the German language. The text was due to Ezzo, the tune to Wille (Müllenhoff and Scherer, *Denkmäler*, i. p. 78, No. 31). A few years later Count Dietrich of Trier began a pilgrimage to Jerusalem with 113 companions, in atonement for the murder of Archbishop Kuno. The ship, however, which conveyed them went down with all hands in a storm (Berth. *Ann.* 1073).

As a result of this steady increase in the number of pilgrims, the old arrangements for their accommodation were found deficient. Consequently hospices arose which were designed exclusively for the pilgrim. Those on the Alpine passes are common knowledge. The oldest, that on the Septimer Pass, dates from the Carolingian period, though it was restored in 1120 by the bishop Wido of Chur: that on the Great St Bernard was founded in the 10th century, and reorganized in the 13th. To this century may also be assigned the hospice on the Simplon; to the 14th those on the St Gothard and the Lukmanier. Similarly, the Mediterranean towns, and Jerusalem in particular, had their pilgrim-refuges. Service in the hospices was regularly performed by the hospital-fraternities—that is to say, by lay associations working under the authorization of the Church. The most important of these was the fraternity of the *Hospitale hierosolymitanum*, founded between 1065 and 1075; for hence arose the order of St John, the earliest of the orders of knighthood. In addition to the hospital of Jerusalem, numerous others were under its charge in Acre, Cyprus, Rhodes, Malta, &c. Associations were formed to assist pilgrims bound for the East; one being the *Confrérie des pèlerins de Terre-Sainte* in Paris, founded in 1325 by Louis de Bourbon, count of Clermont (afterwards first duke of Bourbon). Its church was in the rue des Cordeliers. Similar institutions existed also in Amsterdam, Utrecht, Antwerp and elsewhere in the Netherlands.

But since, in the middle ages, the Holy Land was no longer held by a Christian Power, the protection of the pilgrims was no less necessary than their sustenance. This fact, after the close of the 11th century, led to the Crusades (*q.v.*), which in many respects are to be regarded as armed pilgrimages. For the old dream of the pilgrim, to view the country where God had walked as man, lived on in the Crusades—a fact which is demonstrated by the letters of Bernard of Clairvaux, with the songs of Walther von der Vogelweide and other Crusaders. And, since the strongest motive in the pilgrimage was the acquisition of indulgences, unnumbered thousands were moved to assume the Cross, when, in 1095, Urban II. promised them plenary indulgence (*Conc. Claram.* c. 2). The conquest of Jerusalem, and the erection of a Christian empire in Palestine, naturally welled the influx of pilgrims. And though in 1187 the Holy City again fell into the hands of the infidel, while in 1291 the loss of Acre eliminated the last Christian possession in Palestine, the pilgrimages still proceeded. True, after the fall of the city and the loss of Acre, they were forbidden by the Church; but the veto was impracticable. In the 12th century these religious expeditions were still so common that, every Sunday, prayers were offered in church for the pilgrims (Honor. Aug. *Spec. eccl.* p. 828). In the 13th century the annual number of those who visited Palestine amounted to many thousands: in the 14th and 15th it had hardly shrunk. In fact, between the years 1300 and 1600, no fewer than 1400 men of distinction can be enumerated from Germany alone who travelled to the Holy Land (Röhricht and Meissner, *Deutsche Pilgerreisen*, pp. 465–546). It was not till the Reformation, the wars of the 16th century, and the loss of Rhodes, Candia and Cyprus to the Turks, that any appreciable alteration was effected. When Ignatius de Loyola (*q.v.*) set sail in 1523 from Venice to Palestine, only some thirteen souls could be mustered on the pilgrim-ship, while eight or nine others sailed with the Venetian state-vessel as far as Cyprus. A considerable number had abandoned their pilgrimage and returned home on the news of the fall of Rhodes (Dec. 25, 1522: see *Acta sanct.* Jul. vii. 642 seq.).

For pilgrimage overseas, as it was styled, the permission of the Church was still requisite. The pilgrims made their journey in grey cowls fastened by a broad belt. On the cowl they wore a red cross; and a broad-brimmed hat, a staff, sack and gourd completed their equipment. During their travels the beard was allowed to grow, and they prepared for departure by confession and communion. Of their hymns many are yet extant ("Jerusalem mirabilis," "In gottes namen faren wir," &c.). The embarcation took place either in France or Italy. In France, Marseilles was the main harbour for the pilgrims. From there ships belonging to the Knights of St John and the Knights Templars conducted the commerce with Palestine, and carried annually some 6000 passengers. In the Italian ports the number of shipments was still greater—especially in Venice, whence the regular *passagium* started twice a year. The Venetian pilgrim ships, moreover, carried as many as 1500 souls. The pilgrims formed themselves into unions, elected a "master" and concluded their agreements, as to the outward voyage and return in common. After Venice, Genoa and Pisa occupied the most prominent position. The voyage lasted from six to eight weeks, the stay in Jerusalem averaging ten days. The visitation of the holy places was conducted in processions headed by the Franciscans of the Convent of Zion.

The expenses of the journey to Palestine were no light matter. In the 12th century they may be estimated at 100 marks of silver (£200) for the ordinary pilgrim. This was the amount raised in 1147 by one Goswin von Randerath to defray the expenses of his pilgrimage (*Niederrhein. Urk. Buch.* i. No. 361). Later the cost was put at 280–300 ducats (£140–£150). In the 13th century a knight with two squires, one groom, and the requisite horses, had to disburse 8¼ marks of silver for his passage; while for a single pilgrim the rate was rather less than 1 mark. In the 16th century Ignatius de Loyola calculated the cost of the voyage from Venice to Jaffa at some 6 or 7 gold florins (£3). The expenses of the princes and lords were, of course, much heavier. Duke William of Saxony, who was in Jerusalem in 1461, spent no less than £10,000 on his journey (see Prutz,

gave rise to all manner of religious expeditions. Even among the Israelites, the visitation of certain cult-centres prevailed from remote antiquity; but, when the restriction of Yahweh-worship to Jerusalem had doomed the old shrines, the Jewish pilgrimages were directed solely to the sanctuary on Mt Moria.

Among the Greeks the habit was no less deeply rooted. Just as the inhabitants of each town honoured their tutelar deity by solemn processions to his temple, so, at the period of the Olympic games, the temple of Zeus at Olympia formed the goal of multitudes from every Hellenic country. No less powerful was the attraction exercised by the shrines of the oracular divinities, though the influx of pilgrims was not limited to certain days, but, year in and year out, a stream of private persons, or embassies from the city-states, came flowing to the temple of Zeus in Dodona or the shrine of Apollo at Delphi.

The unification of the peoples of antiquity in the Roman Empire, and the resultant amalgam of religions, gave a powerful impetus to the custom. For, as East and West still met at the old sanctuaries of Greece, so—and yet more—Greece and Rome repaired to the temples of the southern and eastern deities. In the shrine of Isis at Philae, Europeans set up votive inscriptions on behalf of their kindred far away at home, and it may be surmised that even among the festival crowds at Jerusalem a few Greeks found place (John xii. 20).

The pilgrimage, however, attained its zenith under Islam. For Mahomet proclaimed it the duty of every Mussulman, once at least in his life, to visit Mecca; the result being that the birth-place of the Prophet is now the religious centre of the whole Mahommedan world (see MAHOMMEDAN RELIGION; CARAVAN; MECCA).

II. *The Pilgrimage under Christianity.*—The pilgrimages of Christianity presuppose the existence of those of paganism; but it would be an error to maintain that the former were a direct development of the latter. For primitive Christianity was devoid of any point by which these journeys of devotion might naturally have been suggested. It was a religion without temples, without sanctuaries, and without ceremonial. The saying of the Johannine Gospel—that God is to be adored neither in Jerusalem nor on Gerizim, but that His true worshipper must worship Him in spirit and in truth—is in complete harmony with the old Christian piety. And, accordingly, in the ancient Christian literature, we find no trace of a conception that the believer should visit a definite place in order to pay homage to his Master. The evolution of the Christian pilgrimage moved on other lines.

Origin.

Cicero finely observes that, in Athens, the glorious architecture caused him less pleasure than did the thought of the great men whose work was done in its midst—"how here one had lived, and there fallen asleep; how here another had disputed, and there lay buried" (*De Legg.* ii. 2). This feeling was not weakened by the advent of Christianity, in fact, we may say that it was appreciably strengthened. Cicero had already compared the sites consecrated by the memory of some illustrious name with those hallowed by recollections of a loved one. But with the Christian, when his Redeemer was in question, both motives coincided: for there the greatest was also the dearest.

In this devotion to the memory of Jesus, we find the key to the origin of the Christian pilgrimage: the faithful repaired to those places which were invested with memories of their Lord's earthly life. And these journeys must certainly date from the 2nd century. It was there, also, that the scene of the Pentecostal effusion of the Spirit was laid (cf. Cyrill. *Hierus. Cat.* xvi. 4).

The East.

The pilgrimage to Palestine received a powerful impetus from the erection of the memorial churches on the holy sites, under Constantine the Great, as described by Eusebius in his biography of the emperor (iii. 25 sqq.). At the order of Constantine, the shrine of Venus above mentioned was destroyed, and the accumulated rubbish removed, till the ancient rock-foundation was reached. There the cave was discovered in which Joseph of Arimathea had laid the body of Jesus; and above this cave and the Hill of the Crucifixion the imposing church of the Holy Sepulchre was built (A.D. 326–336). The churches in Bethlehem and on the Mount of Olives were erected by Helena, the mother of Constantine, who herself undertook the pilgrimage to the Holy Land. These churches were then endowed with new sanctuaries of miraculous powers; and relics of Christ were found in the shape of the Cross and the nails. Eusebius, the contemporary of Constantine, is silent on this point. To his continuators, on the other hand, it is an established fact that Helena brought all three crosses to light, and ascertained

Fresh pilgrim resorts now began to spring up, and medieval shrines, which had fallen on evil days, to emerge from their obscurity. In the 16th century we must mention the pilgrimages to the "Holy Mount" at Görz on the Austrian coast, and to Montserrat in the Spanish province of Barcelona: in the 17th century, those to Luxemburg, Kevelaer (Gelderland), Notre Dame de Fourvière in Lyons, Heiligenberg in Bohemia, Roermond in the Netherlands, &c. The 18th century, which witnessed the religious *Aufklärung*, was not favourable to the pilgrimage. Enlightened bishops and princes prohibited it altogether: so, for instance, Joseph II. of Austria. Archbishop Clement Wenceslaus of Trier forbade, in 1777, the much-frequented, medieval "leaping-procession" of Echternach (duchy of Luxemburg). The progressive theologians and clergy, moreover, assumed a hostile attitude, and, in 1800, even the Curia omitted the Year of Jubilee. The 19th century, on the other hand, led to an extraordinary revival of the pilgrimage. Not only did new resorts spring into existence—*e.g.* La Salette in Dauphiné (1846), and more particularly Lourdes (1858) in the department of Hautes Pyrénées—but the numbers once more attained a height which enables them to compete with the medieval figures. It is computed that 60,000 pilgrims were present in La Salette on the 29th of September 1847, the first anniversary of the appearance of Mary which gave rise to the shrine. The dedication of the church of Lourdes, in 1876, took place in the presence of 30 bishops, 3000 priests and 100,000 pilgrims. In 1877 the number rose to 250,000; and similar statistics are given of the German and Austrian devotional resorts. The sanctuaries of Aix-la-Chapelle are said to have been visited by 65,000 pilgrims on the 15th of July 1860; and on the following Sunday by 52,000. From 25,000 to 30,000 persons take part each year in the resuscitated "leaping-procession" at Echternach; and the annual visitants to the "Holy Mount" at Görz are estimated at 50,000. No new motives for the pilgrimage emerged in the 19th century, unless the ever-increasing cultus of the Virgin Mary may be classed as such, all of the new devotional sites being dedicated to the Virgin. For the rest, the desire of acquiring indulgences maintains its influence: but doubting voices are no more heard within the pale of the Roman Catholic Church.

PILIBHIT, a town and district of British India, in the Bareilly division of the United Provinces. The town—pop. (1901), 33,490—contains the mosque of Hafiz Rahmat Khan, the Rohilla chieftain, built in the second half of the 18th century. Trade is mainly in agricultural produce, and in the products of the neighbouring Himalayan territory and Nepal.

The DISTRICT OF PILIBHIT has an area of 1350 sq. m.; pop. (1901), 470,339, showing a decrease of 3% in the decade. Though so near the Himalayas it is entirely a plain. In its midst is the Mala swamp. The east is forest-clad, poor and unhealthy; on the other side of the Mala the land becomes more fertile. The chief river is the Sarda, and the Gumti rises in the east. The principal crops are rice, pulses, wheat and sugar-cane. Sugar-refining is carried on, and sugar, wheat, rice and hemp are exported. The Lucknow-Bareilly section of the Oudh & Rohilkhand railway runs through the district, a portion of which is watered by the Rohilkhand canals.

PILLAR (O. Fr. *piler*, Mod. *pilier*, Late Lat. *pilare*, from *pila*, column), an isolated upright structure, of narrow width in relation to its height, which is either employed as a support for a superincumbent load of some sort or is set up for commemorative or ornamental purposes. In the first sense the word has many common applications, as to columns supporting the girders of a warehouse floor or the deckbeams of a ship, to the single central support or pedestal of a table, machine-tool, &c., and to the masses of coal which the miner leaves in certain methods of working as supports to the roof (see COAL); it is also used figuratively of persons in such phrases as a "pillar of the state." In architecture it has strictly the second sense. The column erected in honour of Diocletian at Alexandria is known as Pompey's pillar, and the so-called columns of Trajan and Antoninus are in reality pillars, performing no structural function beyond that of carrying a statue. In India the only example is the iron Pillar at Delhi, which is an extraordinary specimen of the iron-worker's art considering the remote date at which it was made. Up to the middle of the 19th century the term "pillar" was employed to designate the masses of masonry in a church which carry the arcades, but now the term "pier" is invariably adopted in preference.

PILLAU, a seaport and watering-place of Germany, in the Prussian province of East Prussia, on the spit of sand (*Nehrung*) which separates the Frische Haff from the Baltic, on the north of the entrance channel, and 29 m. by rail from Königsberg. Pop. (1905), 7374. It is fortified and has a harbour, which serves as the outer port of Königsberg, and to some extent also of Elbing and Braunsberg. A new navigable channel was in 1900–1901 constructed across the Frische Haff from Pillau to Königsberg. Pillau has a school of navigation, and is a well-known pilot station. Ship-building, sail-making, fishing and the working of amber are carried on.

Pillau is memorable as the place where Gustavus Adolphus of Sweden landed in 1626. It did not obtain civic privileges until 1725, but was fortified shortly after that date. In 1807 it offered a stout resistance to the French. By a treaty of the 24th of February 1812 it was ceded to Napoleon, but on the 6th of February in the following year it was restored to Prussia.

PILLION, a light saddle without pommel or bow, especially a pad fastened to the back of an ordinary saddle, as a seat for another person, generally a woman. Pillions were also used to support baggage. They were in common use from the 16th to the 18th centuries. The word appears to have been adapted into English from the Irish *pillin*, cushion, formed from Lat. *pellis*, skin. In the sense of a hat worn by a priest or doctor of divinity, "pillion" or "pylion" occurs in the 15th and 16th centuries. This is probably from Lat. *pileus*, a conical felt hat or cap, Gr. πῖλος.

PILLNITZ, a village in the kingdom of Saxony, situated on the right bank of the Elbe, 5 m. above Dresden. Pop. (1905), 770. The new palace of the king of Saxony was built in 1818 on the site of a building which was destroyed by fire. The place became a residence of the electors of Saxony about 1700, and the different parts of the palace were erected at various times during the 18th century. By the Convention of Pillnitz in August 1791 the emperor Leopold II. and Frederick William II., king of Prussia, agreed to take common action against any attack on the part of France; this compact may be regarded as the basis of the first coalition against that country.

See A. von Minchwitz, *Geschichte von Pillnitz* (Dresden, 1893).

PILLORY (O. Fr. *pilori*, Prov. *espitlori*, from Lat. *speculatorium*, a place of observation or "peep-hole"), an instrument of punishment which consisted of a wooden post and frame fixed on a platform raised several feet from the ground, behind which the culprit stood, his head and his hands being thrust through holes in the frame (as are the feet in the stocks) so as to be held fast, exposed in front of it. This frame in the more complicated forms of the instrument consisted of a perforated iron circle, which secured the heads and hands of several persons at the same time, but it was commonly capable of holding only one.

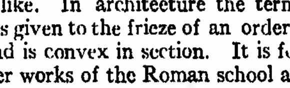
In the statutes of Edward I. it is enacted that every pillory or "stretch-neck" should be made of convenient strength so that execution might be done on offenders without peril of their bodies. It was customary to shave the heads wholly or partially, and the beards of men, and to cut off the hair and even in extreme cases to shave the heads of female culprits. Some of the offences punished in England by the pillory will be found enumerated in

a statute of Henry III. (1266). By this "Statute of the Pillory" it was ordered as the penalty for "forestallers and regrators, users of deceitful weights, perjurers and forgers." Stow, describing Cornhill pillory, says: "On the top of the cage (a strong prison of timber) was placed a pillory for the punishment of bakers offending in the assize of bread, for millers stealing corn at the mill, for bawds, scolds and other offenders." Until 1637 the pillory was reserved for such offenders. In that year an attack was made on the Press, and the pillory became the recognized punishment of those who published books without a licence or libelled the government. Alexander Leighton, John Lilburn, Prynne and Daniel Defoe were among those who suffered. These were popular favourites, and their exposures in the pillory were converted into public triumphs. Titus Oates, however, was put in the pillory in 1685 and nearly killed. In 1816 it was abolished except for perjury and subornation, and the perjurer Peter James Bossy was the last to stand in the pillory at the Old Bailey for one hour on the 22nd of June 1830. It was finally abolished in 1837 at the end of William IV.'s reign. In France the pillory, called *carcan*, was employed till 1832. In Germany it was known as *pranger*. The pillory was used in the American colonies, and provisions as to its infliction existed in the United States statute books until 1839; it survived in the state of Delaware until 1905.

Finger-pillories were at one time in common use as instruments of domestic punishment. Two stout pieces of oak, the top being hinged to the bottom or fixed piece, formed when closed a number of holes sufficiently deep to admit the finger to the second joint, holding the hand imprisoned. A finger-pillory is preserved in the parish church of Ashby-de-la-Zouch, Leicestershire, and there is one, still in its original situation against the wall, at Littlecote Hall, Wilts.

PILLOW (O. Eng. *pylu*; Lat. *pulvinus*, a cushion), a support for the head during sleep or rest. The pillow of Western nations is a cushion of linen or other material, stuffed with feathers, down, hair or wool. In the East it is a framework made of bamboo or rattan with a depression in the top to receive the neck; similarly blocks of wood with a concave-shaped top are used by the natives of other countries. The word is found in various technical uses for a block or support, as for a brass bearing for the journal of a shaft, and the like. In architecture the term "pillowed," or "pulvinated," is given to the frieze of an order which bulges out in the centre and is convex in section. It is found in friezes of some of the later works of the Roman school and is common in Italian practice.

PILOCARPINE, $C_{11}H_{16}N_2O_2$, an alkaloid found, together with isopilocarpine and other related compounds, in the leaves of jaborandi (*Pilocarpus pennatifolius*). It was first isolated by E. Hardy in 1875 (*Ber.*, 8, p. 1594), and is a crystalline, very hygroscopic solid. It is a strong poison. It has the properties of a monacid base and contains the methylamino group, $\cdot NCH_3$. When heated with hydrochloric acid it gives isopilocarpine. Isopilocarpine was isolated in 1900 by H. A. D. Jowett (*Journ. Chem. Soc.* 77, p. 473), and is a colourless oil which boils at 261° C. (10 mm.). It is a monacid base which is readily soluble in solutions of the caustic alkalis. Jowett is of the opinion that pilocarpine and isopilocarpine are stereo-isomers of the structure:—



PILOÑA, a town of northern Spain, in the province of Oviedo; between the right bank of the river Piloña, a left-hand tributary of the Sella, and the Sierra de Abes (3268 ft.). Pop. (1900), 18,228. Though officially classed as a town, Piloña is rather a densely populated mining and agricultural district. It is served by the railway from Infiesto, on the river Piloña, to Oviedo and Gijón.

PILOT, the name applied either to a particular officer serving on board a ship during the course of a voyage and having the charge of the helm and the ship's route, or to a person taken on board at a particular place for the purpose of conducting a ship through a river, road or channel, or from or into a port. The latter kind is the only one to which the term is now applied either in British or foreign countries. The word "pilot" is not the early name for the man who guides or steers a ship. In Old English the name is *lâdman, i.e.* the man who leads the way. "Pilot" does not appear in English till the 16th century. The origin of the word has been much debated. Many etymologists find it in the Dutch *pijloot* (Hexham's *Dictionary*, 1658). This has been identified with *peillood, peil-loth*, sounding lead; cf. German *peilen*, to sound; the last part of these words is the same as English "lead," the metal; the first part, *peilen*, is for *pegelen*, to mark with pegs or points for measuring; cf. *pegel*, gauge. The *New English Dictionary*, on the other hand, finds that the Dutch *piloot*, the earlier form, is taken from the French. The source is, therefore, to be looked for in Romance languages. Du Cange (*Gloss. Med. et Inf. Lat.*) gives *Pedottae*, defined as *quorum est scire intrare et exire portus*, a gloss on *pedotte e timonieri* in F. Ubaldini's edition, 1640, of *I documenti d'amore* by Francesco da Barberino (1264–1348). It is therefore conjectured that the Italian *pilota* is a popular conception of *pedotta*, and a possible source may be found in the Greek πηδόν, oar.

In England, formerly, pilots were subject to the jurisdiction of the lord high admiral; and in the 16th century there are many instances of the Admiralty Court dealing with pilots disciplinarily as well as civilly, holding them liable in damages to owners of ships lost or damaged by their negligence. For some considerable time throughout the United Kingdom the appointment and control of pilots have been in the hands of numerous societies or corporations established at the various ports by charter or act of Parliament, such as the Trinity Houses of Deptford Strond (London), Kingston-upon-Hull, Newcastle-on-Tyne, and Leith, and the Society of Cinque Ports Pilots and Court of Lodemanage (now extinct). These societies had jurisdiction over the pilots exercising their employment within the limits of such ports, and in many cases made it compulsory for ships resorting thither to employ them. By degrees the London Trinity House acquired a leading position, which was confirmed and extended by the general Pilotage Acts passed in the 18th and 19th centuries, with the object of introducing a uniform system throughout the realm. At the present day the United Kingdom is divided into districts for the purpose of pilotage jurisdiction. The (London) Trinity House has jurisdiction over the London district, which extends from Orfordness to Dungeness, and comprises the Thames and Medway up to London and Rochester bridges; the English Channel district, comprising the sea between Dungeness and the Isle of Wight; and the Trinity outport districts, which include any pilotage districts for the appointment of pilots within which no particular provision is made by act of parliament or charter, and the number of which is 40, all English and Welsh. There are 66 other districts, within which other pilotage authorities have jurisdiction.

Authorities.

The present general pilotage law is contained in the Merchant Shipping Acts 1894 to 1906. Pilotage authorities are defined as bodies or persons authorized to appoint or license pilots, or to fix and alter rates of pilotage or to exercise any jurisdiction in respect of pilotage. They are subject to the control of the Board of Trade as the supreme mercantile marine authority. Those bodies, however, which existed at the time of the passing of the act retain their powers and jurisdiction, so far as is consistent with it. The board has power to appoint a new pilotage authority in any area where there is none, and to include a new area where there is none within an already existing one (but in either case pilotage cannot be made compulsory), or to transfer pilotage jurisdiction over a port other than that where the pilotage authority for that port resides, from that pilotage authority to the harbour or other local authority for that port, or to the Trinity House, or to a new authority; and the board has all powers necessary to effectuate such transfer and constitute the new authority. The board may also, by provisional order (which requires parliamentary confirmation), provide for the representation of pilots or shipowners on the pilotage authority

Law.

of any district, and the exemption of ships from compulsory pilotage in any district. Where pilotage is not compulsory, and the power of obtaining pilotage licences unrestricted, the board can in the same way give the pilotage authority powers with respect to licences, amount of pilotage rates, and the like. Pilotage authorities may, by by-laws under the act (which require confirmation by order in council), exempt wholly or partly any ships or classes of ships from compulsory pilotage, and regulate the means of obtaining licences, and the amount of pilotage rates, subject to a maximum limit. They must make yearly returns to the Board of Trade of their by-laws, the names, ages and services of their licensed pilots, the rates of pilotage, the amounts received for pilotage and their receipts and expenditure; and if they fail to do so, the board may suspend their authority, which is then exercised by the Trinity House.

Qualifications. The statutes also provide generally for the qualifications of pilots. A "qualified" pilot is one duly licensed by a pilotage authority to conduct ships to which he does not belong. On his appointment he receives a licence, which is registered with the chief officer of customs at the nearest place to the pilot's residence, and must be delivered up by the pilot whenever required by the licensing pilotage authority. On his death this licence must be returned to that authority. By an act of 1906 no pilotage certificate shall be granted to the master or mate of a British ship unless he is a British subject; this does not, however, refer to the renewal of a certificate granted before 1906 to one not a British subject. Pilotage dues are recoverable summarily from the owner, master, or consignees of the ship, after a written demand for them has been made. A pilot may not be taken beyond the limits of his district without his consent, and if so taken he is entitled to a fixed daily sum in addition to the dues; if he cannot board the ship, and leads her from his boat, he is entitled to the same dues as if he were on board; and he must be truly informed of the ship's draught of water. An unqualified pilot may in any pilotage district take charge of a ship without subjecting himself or his employer to any penalty, where no qualified pilot has offered himself, or where a ship is in distress, or in circumstances where the master must take the best assistance he can, or for the purpose of changing the moorings of any ship in port on docking or undocking her; but after a qualified pilot has offered himself any unqualified pilot continuing in charge, or any master continuing him in charge of the ship, is liable to a penalty. A qualified pilot may not be directly or indirectly interested in licensed premises or in the selling of dutiable goods, or in the unnecessary supply of gear or stores to a ship for his personal gain or for the gain of any other person. He can be punished for quitting a ship before the completion of his duty without the consent of the master, refusing or delaying to perform his duty without reasonable cause when required by lawful authority, lending his licence, acting as pilot when suspended or when intoxicated, and any pilot who through wilful breach of or neglect of duty, or by reason of his drunkenness, endangers ship, life or limb, is guilty of a misdemeanour and liable to suspension or dismissal; but the pilot has an appeal in cases of fines over £2, of suspension or dismissal, suspension or revocation of his licence, or the application of a pilotage fund to which he has contributed. This appeal lies in England to a county court judge having jurisdiction over the port where he is licensed, or a metropolitan police magistrate or stipendiary magistrate with the like power; in Scotland, to a sheriff; in Ireland, to a county court judge, chairman of quarter sessions, recorder, or magistrate. Pilotage certificates may also be granted by pilotage authorities, available within their districts, to masters and mates of ships; and the holder of such a certificate may pilot any ship in respect of which it is available without incurring any penalty for not employing a qualified pilot.

The statute further makes special regulation for Trinity House pilots. Every such pilot, on his appointment, must execute a bond for £100 conditioned for due observance of the Trinity House regulations and by-laws, and thereupon he is not liable for neglect or want of skill to anybody beyond the penalty of the bond and the amount payable to him for pilotage on the voyage on which he was engaged at the time of his so becoming liable. The licence may be revoked or suspended by the Trinity House when it thinks fit; it only continues in force for a year, and the Trinity House has absolute discretion whether it shall be renewed or not.

Pilot Boats and Signals. A pilot boat is approved and licensed by the district pilotage authority who appoints or removes the master thereof. In order to be easily recognized, she has printed on her stern in legible white letters the name of her owner and her port, and on her bows the number of her licence; the remainder of the boat is usually black. The pilot flag is a red and white horizontal flag of a comparatively large size, and is flown from a conspicuous position. When the flag is flown from a merchant vessel, it indicates that a licensed pilot is on board or that the master or mate holds a certificate entitling him to pilot the ship. By order in council of 1900, on and after the 1st day of January 1901 the signals for a pilot displayed together or separately are: In daytime, there is (1) hoisted at the fore the pilot jack (Union Jack having round it a white border, one-fifth of the breadth of the flag); (2) the international code pilotage signal indicated by P.T.; (3) the international code flag S. (white with small blue square centre), with or without the code pennant; (4) the distant signal consisting of a cone point upwards, having above it two balls or shapes resembling balls. By night, (1) the pyrotechnic light commonly known as a blue light, every fifteen seconds; (2) a bright white light, flashed or shown at short or frequent intervals just above the bulwarks, for about a minute at a time.

Compulsory Pilotage. Pilotage in British waters may be either compulsory or free for all or certain classes of ships. From parliamentary pilotage returns, it appears that it is compulsory in about 64 districts of the United Kingdom (of which two-thirds are the Trinity House districts), free in 32, free and compulsory in 8, while in 3 cases (Berwick, Dingwall and Coleraine) no particulars are given. British war-ships in British waters are not compelled to employ a pilot, the navigating officer becoming the pilot under the direction of the captain. If a pilot be employed, the captain and navigating officer are not relieved from responsibility. They supervise the pilot, and should, if necessary, remove him from the ship. In the majority of foreign ports British war-ships are exempted from employing pilots, but the Suez Canal and the ports of France are exceptions. The Merchant Shipping Act 1894 continues the compulsory employment of pilots in all districts where it was already compulsory, and also the already existing exemptions; and there is no power in any pilotage authority or the Board of Trade to increase the area of compulsory pilotage, though there is to diminish it. Compulsion is enforced by a provision in the act, that within a district where compulsory pilotage exists, the master of an unexempted ship who pilots her himself without holding the necessary certificate, after a qualified pilot has offered or signalled to take charge of the ship, shall be liable for each offence to a fine of double the amount of the pilotage dues demandable for the conduct of the ship. The exemptions from compulsory pilotage still existing in British territorial waters are as follows: Ships or vessels with British registers trading to Norway or the Cattegat or the Baltic (except vessels on voyages between any port in Sweden or Norway and the port of London), or round the North Cape, or into the White Sea on their inward or outward voyages, whether coming up by North or South Channels; any constant British traders inwards from ports between Boulogne inclusive and the Baltic coming up by North Channel, and any British ships or vessels trading to ports between the same limits on their outward passages and when coming up by the South Channels; Irish traders using the navigation of the Thames and Medway; ships engaged in the regular coasting trade of the kingdom; ships or vessels wholly laden with stone produced in the Channel Islands and Isle of Man and brought thence; ships or vessels not exceeding 60 tons, whether British or belonging to a foreign country specified by order in council; ships within the limits of the port or place to which they belong, if

this is not a place particularly provided for by act of parliament or charter as regards the appointment of pilots; ships passing through the limits of any pilotage district in their voyages from one port to another port, and not being bound to any port or place within such limits or anchoring therein, but not including ships loading or discharging at any place situate within the district, or at any place situate above the district on the same river or its tributaries. Ships whose masters or mates are owners or part-owners of them, and living at Dover, Deal, or the Isle of Thanet, may be piloted by them from any of these places up and down the Thames or Medway, or into or out of any place or port within the jurisdiction of the Cinque Ports. The following ships in the London district and Trinity outport districts are also exempt when not carrying passengers, namely: Ships employed in the coasting trade of the United Kingdom; ships of not more than 60 tons burden; ships trading to or from any port in Great Britain within the above districts to or from the port of Brest in France, and any port in Europe (which does not include the United Kingdom) north and east of Brest, or to the Channel Islands or Isle of Man; and ships navigating within the limits of the port to which they belong. The port to or from which the ship must be "trading" in this provision has been interpreted by the decisions to mean the port where the cargo is substantially discharged or loaded respectively; and the word "coaster" similarly has been held to apply only to a vessel carrying to one port of the United Kingdom a cargo which has been taken in at another. Every ship carrying passengers between any place in the British Islands and any other place so situate must carry a compulsory pilot, unless her master or mate have a pilotage certificate. The effect in law of the ship (British or foreign) being in charge of a compulsory pilot under the act is that her owner and master are not answerable to any person whatever for any loss or damage occasioned by the fault or incapacity of any qualified pilot acting in charge of such ship within any district where the employment of such pilot is compulsory by law. In order to take advantage of this privilege, the shipowner must show (1) that a properly qualified pilot was acting in charge of the ship; there are, however, various kinds of qualified pilots—the qualified pilot who is always capable of acting, and the qualified pilot who is liable to be superseded if a better can be obtained; (2) that that charge was compulsory; the pilot, however, need not be compulsorily employed at the place where the accident happened, so long as he is compulsorily employed within the district where it happens; (3) that it was solely the pilot's fault or incapacity which caused the damage. Similarly, under the Harbours, Piers and Docks Clauses Act, the owner of a vessel is not liable for damage done thereby to docks or piers when she is in charge of a duly licensed pilot.

This statutory exemption of a ship in charge of a compulsory pilot from any liability for her negligent navigation by that pilot, is only declaratory of the common law of England, and is based on the principle that the pilot is a state official put in charge of a ship, and is not the servant of the shipowner so as to make him liable for his negligence; and a British court gives the same effect to any foreign or colonial law which makes it compulsory on shipowners to put a pilot in charge of their ship when within their jurisdiction. Most foreign codes, however, while agreeing with English law in making the presence of a pilot on board compulsory, differ from it in not putting him in charge of the ship; and in this case the defence of compulsory pilotage cannot be pleaded successfully in British courts. Judicial decisions have established that French, Suez Canal, Danube and Dutch pilots are not compulsory pilots in the British sense of the word, being only advisers of the master, or "living charts." But if the pilot is put in charge by the foreign or colonial law, although that law expressly provides that in spite of the owner surrendering the charge of the ship to him the owner shall still remain liable, a British court will hold the owner free from liability, on the ground that to make any person liable for a tort committed abroad, the act complained of must be wrongful not only according to the foreign law, but also by English law. This consequence which English law attaches to the employment of a compulsory pilot has been much criticized in recent times, and it would seem that the foreign view is much more satisfactory in regarding the pilot merely as the adviser and not the superior of the master. Moreover, the adoption of the foreign law on this point would restore the old general maritime law. The policy of the law was at one time inclined to extend this principle of compulsory pilotage, on the ground that it was for the benefit of commerce and the safety of seamen's lives, but it now restricts it within as narrow limits as possible, *e.g.* the presence of a compulsory pilot on board a tow who is directing the navigation of a tug does not protect the tug-owner from liability for negligent navigation. As already pointed out, pilotage authorities have no power to extend its scope.

A pilot who is compulsorily in charge of a ship under English law has supreme control over her navigation, superseding the master for the time being; and if she is a tow he has also control of the navigation of her tug. The judicial decisions establish that it is within his province to decide whether the ship shall get under way, the proper time and place for her to anchor, the way of carrying her anchor, the proper orders for the helm, her rate of speed, and whether the statutory rules of navigation shall be complied with; and the master and crew must not interfere with his control, and only remain liable for the proper execution of the pilot's orders and the trim and general efficiency as to look-out, &c., of the ship. The master, however, is bound to supersede the pilot in case of his intoxication or manifest incapacity, and to interfere if there is a clear and plain prospect of danger to the ship in following the pilot's directions, *e.g.* getting under way in a thick fog. The pilot is entitled to receive from the master assistance in having his attention called to anything which a competent mariner would see that he ought to know. A pilot taken voluntarily, and not by compulsion of law, is considered as the servant of the shipowner, and as such renders him liable for his acts of negligence towards third parties. He does not, it seems, supersede the master in the control of the ship, but only advises him. The Admiralty and the Board of Trade and the Trinity House all take the view that the captain or master is bound to keep a vigilant eye on the navigation of the vessel by the pilot, and insist on all proper precautions being taken. For the purposes of a policy of marine insurance a ship is not seaworthy without a pilot in compulsory pilotage waters; and where there is no legal compulsion to have one, but the locality requires navigation by a person having local knowledge, it has been said that a ship must take a pilot, certainly when leaving a port, and probably on entering a port if a pilot is available.

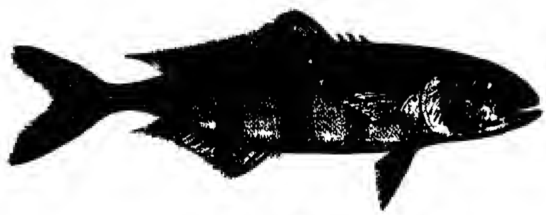
A pilot can sue for his pilotage fee at common law or in Admiralty (*q.v.*), in the latter case provided that the contract was made and the work done not within the body of a county; but he has a summary remedy by statute which is of easier application. He cannot be sued in Admiralty for damage done by a collision caused by his negligence (*e.g.* on the Admiralty side of a county court having Admiralty jurisdiction); but he can be made liable at common law or in the Admiralty Division of the High Court, although in the case of a Trinity House pilot his liability is limited to the amount of his bond and pilotage fee then being earned (see above); but the court has refused to join him as a defendant to an action *in rem* brought against the ship of which he had the charge. A pilotage authority cannot be made liable for the negligent navigation of a ship by a pilot which it has licensed, for he is not its servant, though it has been held liable for the negligence of a person not licensed by it as a pilot, but employed by it for wages to pilot ships into a harbour under its jurisdiction, itself taking the pilotage dues and applying them for harbour purposes. A pilot is not in common employment with the master and crew of a ship, and can recover for any injury done him by their negligence. He may be entitled to claim salvage from a ship of which he has charge, if the services he renders are beyond the scope of his pilotage contract, either from the outset or owing to supervening circumstances, but not otherwise, whether he is on board her or leading her from his boat. (See SALVAGE.)

In the *United States* pilotage laws are regulated by the respective

states. If the waters are the boundary between two states a duly licensed pilot of either state may be employed, but no discrimination can be made in the rates of pilotage between vessels of different states. In the *German Empire* the pilotage laws are very complicated. In the majority of the maritime states each one has its own regulations and laws. In *Prussia* there are government pilots who enter the service as apprentices, and are placed under a department of state. In *France* the general organization of pilots is regulated by the Statute on Pilots of the 12th of December 1806, and the pilotage regulations for each port are made by the minister of marine at the request of his local representative and the Chamber of Commerce. French pilots are exempt from military service.

See Abbott, *Shipping* (London, 1901); Maude and Pollock, *Shipping* (London, 1881); Marsden, *Collisions at Sea* (London, 1910); *Select Pleas of the Admiralty* (Selden Society, London, 1892 and 1897); Temperley, *Merchant Shipping Acts* (1907); Twiss, *Black Book of Admiralty* (London, 1871). (G. G. P.*; J. W. D.)

PILOT-FISH (*Naucrates ductor*), a pelagic fish of the family of horse-mackerels or *Carangidae*, well known to sailors from its peculiar habit of keeping company with ships and large fishes, especially sharks. It occurs in all tropical and sub-tropical seas, and is common in the Mediterranean, but becomes scarcer in higher latitudes. In summer pilots will accompany ships as far north as the south coast of England into port. This habit was known to the ancients, who describe the *Pompilus* as



Pilot-fish.

a fish which points out the way to dubious or embarrassed sailors, and by its sudden disappearance indicates to them the vicinity of land; the ancient seamen of the Mediterranean regarded it, therefore, as a sacred fish. That the pilot accompanies sharks is an observation which first appears in works of travel of the 17th century, the writers asserting that it is of great use to its big companion in conducting it and showing it the way to its food. It is, however, extremely doubtful whether the pilot's connexion with a shark serves a more special purpose than its temporary attachment to a ship. It accompanies both on account of the supply of food which it derives from them. The pilot, therefore, stands to both in the relation of a so-called "commensal," like the *Echeneis* or sucking-fish. All observers, however, agree that neither the pilot nor the sucker is ever attacked by the shark. The pilot attains to a length of about 12 in. In the shape of its body it resembles a mackerel, but is rather shorter, especially in the head, and covered with small scales. A sharp keel runs along the middle of each side of the tail. The first dorsal fin consists of a few short spines not connected by a membrane; the second dorsal and the anal are composed of numerous rays. The teeth, which occupy the jaws, vomer and palatine bones, are all small, in villiform bands. The coloration of the pilot renders it conspicuous at a distance; on a bluish ground-colour from five to seven dark-blue or violet cross-bands traverse the body from the back to the belly. The pilot-fish spawns in the open sea, and its fry is constantly caught in the tow-net. But young pilot-fish differ considerably from the adult, having the spines of the first dorsal connected by a membrane, and some bones of the head armed with projecting spines. These little fishes were therefore long considered to be a distinct genus, *Nauclerus*.

PILOTY, KARL VON (1826–1886), German painter, was born at Munich, on the 1st of October 1826. His father, Ferdinand Piloty (d. 1844), enjoyed a great reputation as a lithographer. In 1840 he was admitted as a student of the Munich Academy, under the artists Schorn and Schnorr. After a journey to Belgium, France and England, he commenced work as a painter of genre pictures, and in 1853 produced a work, *Die Amme* ("The Wet Nurse"), which, on account of its originality of style, caused a considerable sensation in Germany at the time. But he soon forsook this branch of painting in favour of historical subjects, and produced in 1854, for King Maximilian II., "The Adhesion of Maximilian I. to the Catholic League in 1609." It was succeeded by "Seni at the Dead Body of Wallenstein" (1855), which gained for the young painter the membership of the Munich Academy, where he succeeded Schorn (his brother-in-law) as professor. Among other well-known works by Piloty are the "Battle of the White Mountain near Prague," "Nero Dancing upon the Ruins of Rome" (1861), "Godfrey of Bouillon on a Pilgrimage to the Holy Land" (1861), "Galileo in Prison" (1864), and "The Death of Alexander the Great" (unfinished), his last great work. He also executed a number of mural paintings for the royal palace in Munich. For Baron von Schach he painted the justly celebrated "Discovery of America." In 1874 he was appointed keeper of the Munich Academy, being afterwards ennobled by the king of Bavaria. Piloty was the foremost representative of the realistic school in Germany. He was a most successful teacher, and among his more famous pupils may be mentioned Makart, Lenbach, Defregger, Max and Grützner. He died at Munich on the 21st of July 1886.

PILSEN (Czech, *Plzeň*), a town of Bohemia, Austria, 68 m. W.S.W. of Prague by rail. Pop. (1900), 68,292, of which 94 % are Czech. It is the second town of Bohemia, and lies at the confluence of the Radbusa and the Mies. It consists of the town proper, which is regularly built and surrounded with promenades on the site of the old ramparts, and of three suburbs. The most prominent buildings are the Gothic church of St Bartholomew, said to date from 1292, whose tower (325 ft.) is the highest in Bohemia, and the fine Renaissance town hall dating from the 16th century. The staple article of manufacture and commerce is beer, which is exported to all parts of the world. Other industrial products are machinery, enamelled tinware, leather, alum, paper, earthenware, stoves and spirits, while a tolerably brisk trade is carried on in wool, feathers, cattle and horses. In the neighbourhood are several coal-pits, iron-works and glass-works, as well as large deposits of kaolin.

Pilsen first appears in history in 976, as the scene of a battle in the war between Prince Boleslaus and the emperor Otto II., and it became a town in 1272. During the Hussite Wars it was the centre of Catholic resistance to the Hussites; it was three times unsuccessfully besieged by Prokop the Great, and it took part in the league of the Romanist lords against King George of Podebrad. During the Thirty Years' War the town was taken by Mansfield in 1618 and not recaptured by the Imperialists till 1621. Wallenstein made it his winter quarters in 1633, and it was in the great hall of the *Rathaus* that his generals took the oath of fidelity to him (January 1634). The town was unsuccessfully besieged by the Swedes in 1637 and 1648. The first Bohemian printing press was established here in 1468.

PIMA, a tribe and stock of North American Indians. Their range was southern Arizona and northern Mexico. The ruined Pima village, known to the Spanish as Casa Grande on the south bank of the Gila, is an example of their early civilization and skill in building. Driven out of their homes by neighbouring tribes, they lived a more or less nomadic life. They were always good farmers, showing much skill in irrigation. At first submitting to the Spaniards, they revolted in 1751, destroying all the missions. The war lasted two years, but since then the Pima Indians have been friendly with the settlers. As a race they are brave, honest and hard working. They number some 5000 on two reservations in Arizona. The Piman stock includes such tribes as the Papago, Huichol, Opata, Tarumari, and numbers upwards of a hundred thousand.

PIMENTO, also called ALLSPICE (from a supposed combination of various flavours) and JAMAICA PEPPER, the dried immature fruit of *Eugenia pimenta* or *Pimenta officinalis*, an evergreen tree about 30 ft. high, belonging to the natural order *Myrtaceae*. It is indigenous in the West India Islands, growing on limestone hills near the sea, and is especially grown in Jamaica. The spice derives its name from the Portuguese *pimenta*, Spanish *pimienta*, pepper, which was given to it from its resemblance to

pepper-corns. The berries are gathered in July and August, when of full size, but still unripe—the small branches bearing fruit being broken off and dried in the sun and air for some days, when the stalks are removed and the berries are ready for packing. These owe their aromatic properties to an essential oil present to the extent of 3 to 4½ % and consisting largely of eugenol or allyl guaiacol, $HO(CH_3O)C_6H_3 \cdot C_3H_5$. The chief use of pimento is as a spice. The oil, the action of which resembles that of cloves, is occasionally used in medicine, and is also employed in perfuming soaps. The "bay rum" used as a toilet article is a tincture scented with the oil of the leaves of an allied species, *Pimenta acris*, commonly known as the bayberry tree.

PIN (a doublet with "pen" from Lat. *pinna*, feather, pinnacle, which is said to contain the same root as πίτυς, pine tree, and properly to mean a sharp point or end), a small peg or bolt of metal or wood, not necessarily pointed, employed as a fastening to connect together different parts of an article, as a stop to limit the motion of some moving piece in a machine, as a support on which a small wheel may turn, &c., but most commonly a small metal spike, used for fastening portions of fabrics together, having one end pointed and at the other a bulbed head, or some other arrangement for preventing the spike from passing entirely through the cloth or other material with which it is employed. In one form or another pins of this last kind are of the highest antiquity, the earliest form doubtless being a natural thorn. Pins of bronze, and bronze brooches in which the pin is the essential feature, are of common occurrence among the remains of the bronze age. The ordinary domestic pin had become in the 15th century an article of sufficient importance in England to warrant legislative notice, as in 1483 the importation of pins was prohibited by statute. In 1540 Queen Catherine received pins from France, and again in 1543 an act was passed providing that "no person shall put to sale any pinnes but only such as shall be double headed, and have the heads soldered fast to the shank of the pinnes, well smoothed, the shank well shapen, the points well and round filed, canted and sharpened." At that time pins of good quality were made of brass; but a large proportion of those against which the legislative enactment was directed were made of iron wire blanched and passed as brass pins. To a large extent the supply of pins in England was received from France till about 1626, in which year the manufacture was introduced into Gloucestershire by John Tilsby. His business flourished so well that he soon gave employment to 1500 persons, and Stroud pins attained a high reputation. In 1636 the pinmakers of London formed a corporation, and the manufacture was subsequently established at Bristol and Birmingham, the latter town ultimately becoming the principal centre of the industry. So early as 1775 the attention of the enterprising colonists in Carolina was drawn to the manufacture by the offer of prizes for the first native-made pins and needles. At a later date several pin-making machines were invented in the United States. During the war of 1812, when the price of pins rose enormously, the manufacture was actually started, but the industry was not fairly successful till about the year 1836 when the Howe Manufacturing Company was formed at Birmingham, Connecticut. Previous to this an American, Lemuel W. Wright, had in 1824 secured in England a patent for a machine to make solid-headed pins, which established the industry on its present basis.

The old form of pin consisted of a shank with a separate head of fine wire twisted round and secured to it. Fine wire for heads was first wound on a lathe round a spit the exact circumference of the pin shanks to be headed. In this way a long elastic spiral was produced which had next to be cut into heads, each consisting of two complete turns of the spiral. These heads were softened by annealing and made into a heap for the heading boy, whose duty was to thrust a number of shanks into the heap and let as many as might be fit themselves with heads. Such shanks as came out thus headed were passed to the header, who with a falling block and die arrangement compressed together shank and head of such a number as his die-block was fitted for. All the other operations of straightening the wire, cutting, pointing, &c., were separately performed, and these numerous details connected with the production of a common pin were seized on by Adam Smith as one of the most remarkable illustrations of the advantages of the division of labour

The beautiful automatic machinery by which pins are now made of single pieces of wire is an invention of the 19th century. In 1817 a communication was made at the Patent Office by Seth Hunt, describing a machine for making pins with "head, shaft and point in one entire piece." By this machine a suitable length of wire was cut off and held in a die till a globular head was formed on one end by compression, and the other end was pointed by the revolution around it of a roughened steel wheel. This machine does not appear to have come into use; but in 1824 Wright patented the pin-making apparatus above referred to as the parent form of the machinery now employed. A factory equipped with his machines was established in London, but the company which owned it was not successful. The plant passed into the hands of Daniel Foote-Tayler of Birmingham, who obtained an extension of Wright's patent for five years from 1838, and his firm was the first to carry on the production of machine-made solid-headed pins on a commercial basis. In a modern pin-making machine wire of suitable gauge running off a reel is drawn in and straightened by passing between straightening pins or studs set in a table. When a pin length has entered it is caught by lateral jaws, beyond which enough of the end projects to form a pin-head. Against this end a steel punch advances and compresses the metal by a die arrangement into the form of a head. The pin length is immediately cut off and the headed piece drops into a slit sufficiently wide to pass the wire through but retain the head. The pins are consequently suspended by the head while their projecting extremities are held against a revolving cutter, by which they are pointed. They are next cleaned by being boiled in weak beer, and then arranged in a copper pan in layers alternating with layers of grained tin. The contents of the pan are covered with water over which a quantity of argol (bitartrate of potash) is sprinkled, and after boiling for several hours the brass pins are coated with a thin deposit of tin, which gives them their silvery appearance. They are then washed in clean water, and dried and polished by being revolved in a barrel, mixed with dry bran or fine sawdust, from which they are winnowed finished pins. A large proportion of the pins sold are stuck into paper by an automatic machine not less ingenious than the pin-making machine itself. Mourning pins are made of iron wire, finished by immersing in black japan and drying in a stove. A considerable variety of pins, including the ingeniously coiled, bent and twisted nursery safety pin, ladies' hairpins, &c., are also made by automatic machinery. The sizes of ordinary pins range from the 3½-in. stout blanket pin down to the finest slender gilt pin used by entomologists, 4500 of which weigh about an ounce.

PINA, RUY DE (1440–1521), Portuguese chronicler, was a native of Guarda. He acted as secretary of the embassy sent by King John II. to Castile in the spring of 1482, and in the following September returned there as sole envoy. He was present at the execution of the duke of Braganza at Evora in 1483, and in 1484 went to Rome as secretary of an embassy to Pope Innocent VII. On his return, the king charged him to write a history of his reign and gave him a pension for his support. Following the arrival of Columbus from his first voyage in 1493, Pina was one of the commissaries despatched to Barcelona by John II. to negotiate with the Catholic sovereigns respecting the limits of their respective jurisdictions. In September 1495 he attested the will of John II. in his capacity as a notary public, and on the 25th of October of the same year he was present at his master's death at Alvor and opened and read his testament. King Manoel confirmed his pension and appointed him in 1497 chronicler of the kingdom, keeper of the archives and royal librarian, with a suitable salary. By 1504 Pina had completed his chronicles of Alphonso V. and John II. King John III. charged him with a history of his father, Manoel, and at his death Pina had carried it down to the capture of Azamor, as we know from Damião de Goes, who used it in preparing his own chronicle of that monarch.

It is probable that the chronicles of the early kings of Portugal from Sancho I. to Alphonso IV. which were published under Pina's name in the 18th century were written by Fernão Lopes and edited by Pina, while that of King Duarte seems to have been the joint production of Lopes and Azurara, with Pina again as the editor only. Pina was a favourite of fortune during his life, for, apart from royal benefactions, he received presents from public men who wished to figure well in his books, and after his death he obtained the credit for work that was not his. His authority as an historian is considerable, and his frankness is said to have provoked remark from contemporaries.

Pina's chronicle of King Alphonso IV. was first published in Lisbon in 1853; those of King Duarte and King Alphonso V. in vol. i. of the *Collecão de livros ineditos da historia portugueza*

(Lisbon, 1790), and his chronicle of John II. in vol. ii. of the same collection (Lisbon, 1792). The introduction to the chronicle of King Duarte contains the fullest account of Pina's life. (E. Pr.)

PINACOTHECA, a picture-gallery (Gr. πινακοθήκη, from πίναξ, a tablet or picture). The name is especially given to the building containing pictures which formed the left wing of the Propylaea on the Acropolis at Athens. Though Pausanias (Bk. II., xxii. 6) speaks of the pictures "which time had not effaced," which seems to point to fresco painting, the fact that there is no trace of any preparation for stucco on the walls rather shows that the paintings were easel pictures (J. G. Frazer, *Pausanias's Description of Greece*, 1898, ii. 252). The Romans adopted the term for the room in a private house containing pictures, statues, and other works of art. It is used for a public gallery on the continent of Europe, as at Bologna and Turin. At Munich there are two galleries known as the Old and New Pinakothek.

PINAR DEL RIO, capital of Pinar del Rio Province, Cuba, about 107 m. S.W. by railway from Havana. Pop. (1907), 10,634. The city is in the fertile valley of the Guama. It is the centre of the tobacco industry of the Vuelta Abajo region. Its port is La Coloma, on the southern coast. The pueblo was created after 1773; but the history of the settlement goes back to 1571, and the parochial church dates from 1710.

PINCKNEY, CHARLES (1757–1824), American statesman, was born on the 26th of October 1757 at Charleston, South Carolina; he was the son of Charles Pinckney (1731–1784), first president of the first South Carolina Provincial Congress (Jan. to June 1775), and a cousin of Charles Cotesworth Pinckney and Thomas Pinckney. He was studying law at the outbreak of the War of Independence, served in the early campaigns in the south, and in 1779 was elected to the South Carolina house of representatives. He was captured by the British at the fall of Charleston (1780), and remained a prisoner until the close of hostilities. He was elected a delegate to the Congress of the Confederation in 1784, 1785 and 1786, and in 1786 he moved the appointment of a committee "to take into consideration the affairs of the nation," advocating in this connexion an enlargement of the powers of Congress. The committee having been appointed, Pinckney was made chairman of a sub-committee which prepared a plan for amending the articles of confederation. In 1787 he was a delegate to the Federal constitutional convention, and on the same day (May 29) on which Edmund Randolph (*q.v.*) presented what is known as the Virginia plan, Pinckney presented a draft of a constitution which is known as the Pinckney plan. Although the Randolph resolutions were made the basis on which the new constitution was framed, Pinckney's plan seems to have been much drawn upon. Furthermore, Pinckney appears to have made valuable suggestions regarding phrasing and matters of detail. On the 18th of August he introduced a series of resolutions, and to him should probably be accredited the authorship of the substance of some thirty-one or thirty-two provisions of the constitution.[1] Pinckney was president of the State Convention of 1790 that framed a new constitution for South Carolina, was governor of the state from 1789 to 1792, a member of the state house of representatives in 1792–1796, and again governor 1796–1798. From 1799 to 1801 he was a member of the United States Senate. He entered public life as a Federalist, but later became the leader in organizing the Democratic-Republican party in his state, and contributed largely to the success of Thomas Jefferson in the presidential election of 1800. By Jefferson's appointment he was American minister to Spain from 1801 to 1805. In general his mission was a distinct failure, his arrogance and indiscretions finally causing the Spanish government to request his recall. He was elected to the state house of representatives in 1805, was again governor of South Carolina from 1806 to 1808, in 1810–1814 was once more a member of the state house of representatives, in which he defended President Madison's war policy, and from 1819 to 1821 was a member of the National House of Representatives, in which he opposed the Missouri Compromise in a brilliant speech. He died at Charleston, South Carolina, on the 29th of October 1824.

His son, Henry Laurens Pinckney (1794–1863), was a member of the state house of representatives in 1816–1832, founded in 1819 and edited for fifteen years the Charleston *Mercury*, the great exponent of state's rights principles, and was a member of the National House of Representatives in 1833–1837.

PINCKNEY, CHARLES COTESWORTH (1746–1825), American statesman, was born in Charleston, South Carolina, on the 25th of February 1746, the son of Charles Pinckney (d. 1758),[2] by his second wife, the celebrated girl planter, Eliza Lucas. When a child he was sent to England, like his brother Thomas after him, to be educated. Both of them were at Westminster and Oxford and were called to the bar, and for a time they studied in France at the Royal Military College at Caen. Returning to America in 1769, C. C. Pinckney began the practice of law at Charleston, and soon became deputy attorney-general of the province. He was a member of the first South Carolina provincial congress in 1775, served as colonel in the South Carolina militia in 1776–1777, was chosen president of the South Carolina senate in 1779, took part in the Georgia expedition and the attack on Savannah in the same year, was captured at the fall of Charleston in 1780 and was kept in close confinement until 1782, when he was exchanged. In 1783 he was commissioned a brevet brigadier-general in the continental army. He was an influential member of the constitutional convention of 1787, advocating the counting of all slaves as a basis of representation and opposing the abolition of the slave-trade. He opposed as "impracticable" the election of representatives by popular vote, and also opposed the payment of senators, who, he thought, should be men of wealth. Subsequently Pinckney bore a prominent part in securing the ratification of the Federal constitution in the South Carolina Convention called for that purpose in 1788 and in framing the South Carolina State Constitution in the convention of 1790. After the organization of the Federal government, President Washington offered him at different times appointments as associate justice of the Supreme Court (1791), secretary of war (1795) and secretary

[1] The "Pinckney Plan" has been the subject of considerable discussion. When, in 1818, John Quincy Adams was preparing the journal of the convention for publication and discovered that the Pinckney plan was missing, he wrote to Pinckney for a copy, and Pinckney sent him what he asserted was either a copy of his original draft or a copy of a draft which differed from the original in no essentials. But as this was found to bear a close resemblance to the draft reported by the committee of detail, Madison and others, who had been members of the convention, as well as historians, treated it as spurious, and for years Pinckney received little credit for his work in the convention. Later historians, however, notably J. Franklin Jameson and Andrew C. McLaughlin, have accredited to him the suggestion of a number of provisions of the constitution as a result of their efforts to reconstruct his original plan chiefly from his speeches, or alleged speeches, and from certain papers of James Wilson, a member of the committee of detail, one of which papers is believed to be an outline of the Pinckney plan. See J. F. Jameson, "Studies in the History of the Federal Convention of 1787," in the *Annual Report of the American Historical Association for 1902*, vol. i.; A. C. McLaughlin, "Outline of Pinckney's Plan for a Constitution," in *The Nation*, April 28, 1904; an article entitled "Sketch of Pinckney's Plan for a Constitution," in the *American Historical Review* for July 1904; and C. C. Nott, *The Mystery of the Pinckney Draught* (New York, 1908), an attempt by a former chief justice of the U.S. Court of Claims to prove that the document sent by Pinckney to Adams in 1818 is a genuine copy of his original plan.

[2] Charles Pinckney, the father, was long prominent in colonial affairs; he was attorney-general of the province in 1733, speaker of the assembly in 1736–1738 and in 1740, chief justice of the province in 1752–1753, and agent for South Carolina in England in 1753–1758. He was the uncle of Charles Pinckney (1731–1784), and the great-uncle of Charles Pinckney (1757–1824). Eliza Lucas Pinckney (*c.* 1722–1793) was the daughter of Lieut.-Colonel George Lucas of the British army, who about 1738 removed from Antigua to South Carolina, where he acquired several plantations. He was almost immediately recalled to Antigua, and his daughter undertook the management of the plantations with conspicuous success. She is said to have been the first to introduce into South Carolina (and into continental North America) the cultivation and manufacture of indigo, and she also imported silkworms—in 1753 she presented to the princess of Wales a dress made of silk from her plantations. She was married to Charles Pinckney in 1744. See Harriott H. Ravenel, *Eliza Pinckney* (New York, 1896), in the "Women of Colonial and Revolutionary Times" series.

of state (1795), each of which he declined; but in 1796 he succeeded James Monroe as minister to France. The Directory refused to receive him, and he retired to Holland, but in the next year, Elbridge Gerry and John Marshall having been appointed to act with him, he again repaired to Paris, where he is said to have made the famous reply to a veiled demand for a "loan" (in reality for a gift), "Millions for defence, but not one cent for tribute,"—another version is, "No, not a sixpence." The mission accomplished nothing, and Pinckney and Marshall left France in disgust, Gerry (*q.v.*) remaining. When the correspondence of the commissioners was sent to the United States Congress the letters "X," "Y" and "Z," were inserted in place of the names of the French agents with whom the commission treated—hence the "X Y Z Correspondence," famous in American history. In 1800 he was the Federalist candidate for vice-president, and in 1804 and again in 1808 for president, receiving 14 electoral votes in the former and 47 in the latter year. From 1805 until his death, on the 16th of August 1825, he was president-general of the Society of the Cincinnati.

PINCKNEY, THOMAS (1750–1828), American statesman and diplomat, was born in Charleston, South Carolina, on the 23rd of October 1750, a younger brother of Charles Cotesworth Pinckney (*q.v.*). Educated in England, he returned to Charleston in 1773, and was admitted to the bar in 1774. During the War of Independence his early training at the French military college at Caen enabled him to render effective service to General Benjamin Lincoln in 1778–1779, to Count d'Estaing (1779), to General Lincoln in the defence of Charleston and afterwards to General Horatio Gates. In the battle of Camden he was badly wounded and captured, remaining a prisoner for more than a year. Subsequently he was governor of South Carolina in 1787–1789; presided over the state convention which ratified the Federal constitution in 1788; was a member of the state legislature in 1791; and was United States minister to Great Britain in 1792–1796. During part of this time (1794–1795) he was also envoy extraordinary to Spain, and in this capacity negotiated (1795) the important Treaty of San Lorenzo el Real; by that treaty the boundary between the United States and East and West Florida and between the United States and "Louisiana" was settled (Spain relinquishing all claims east of the Mississippi above 31° N. lat.), and the United States secured the freedom of navigation of the Mississippi to its mouth with the right of deposit at New Orleans for three years, after which the United States was to have the same right either at New Orleans or at some other place on the Mississippi to be designated by Spain. In 1796 Pinckney was the Federalist candidate for vice-president, and in 1797–1801 he was a Federalist representative in Congress. During the war of 1812 he was a major-general. In 1825 he succeeded his brother as president-general of the Society of the Cincinnati. He died in Charleston on the 2nd of November 1828. Pinckney, like many other South Carolina revolutionary leaders, was of aristocratic birth and politics, closely connected with England by ties of blood, education and business relations. This renders the more remarkable their attitude in the War of Independence, for which they made great sacrifices. Men of Pinckney's type were not in sympathy with the progressive democratic spirit of America, and they began to withdraw from politics after about 1800.

See C. C. Pinckney, *Life of General Thomas Pinckney* (Boston, 1895).

PINDAR (Gr. Πίνδαρος, *c.* 522–443 B.C.), the great lyric poet of ancient Greece, was born at Cynoscephalae, in Boeotia, at the time of the Pythian games (*fr.* 175, Bergk⁴, 193),[1] which is taken by Böckh to be 522 B.C. He would thus be some thirty-four years younger than Simonides of Ceos. He was the son of Daiphantus and Cleodice (or Cleidice). The traditions of his family have left their impress on his poetry, and are not without importance for a correct estimate of his relation to his contemporaries. The clan of the Aegidae—tracing their line from the hero Aegeus—belonged to the "Cadmean" element of Thebes, *i.e.* to the elder nobility whose supposed date went back to the days of the founder Cadmus. A branch of the Theban Aegidae had been settled in Achaean times at Amyclae in the valley of the Eurotas (Pind. *Isthm.* vi. 14), and after the Dorian conquest of the Peloponnesus had apparently been adopted by the Spartans into one of the three Dorian tribes. The Spartan Aegidae helped to colonize the island of Thera (*Pyth.* v. 68–70). Another branch of the race was settled at Cyrene in Africa; and Pindar tells how his Aegid clansmen at Thebes "showed honour" to Cyrene as often as they kept the festival of the Carnea (*Pyth.* v. 75). Pindar is to be conceived, then, as standing within the circle of those families for whom the heroic myths were domestic records. He had a personal link with the memories which everywhere were most cherished by Dorians, no less than with those which appealed to men of "Cadmean" or of Achaean stock. And the wide ramifications of the Aegidae throughout Hellas rendered it peculiarly fitting that a member of that illustrious clan should celebrate the glories of many cities in verse which was truly Panhellenic.

Pindar is said to have received lessons in flute-playing from one Scopelinus at Thebes, and afterwards to have studied at Athens under the musicians Apollodorus (or Agathocles) and Lasus of Hermione. In his youth, as the story went, he was defeated in a poetical contest by the Theban Corinna—who, in reference to his profuse employment of Theban mythology, is said to have advised him "to sow with the hand, not with the sack." There is an extant fragment in which Corinna reproves another Theban poetess, Myrtis, "for that she, a woman, contended with Pindar" (ὅτι βανὰ φοῦσ' ἔβα Πινδάροιο ποτ' ἔριν) —a sentiment which hardly fits the story of Corinna's own victory. The facts that stand out from these meagre traditions are that Pindar was precocious and laborious. Preparatory labour of a somewhat severe and complex kind was, indeed, indispensable for the Greek lyric poet of that age. Lyric composition demanded studies not only in metre but in music, and in the adaptation of both to the intricate movements of the choral dance (ὀρχηστική). Several passages in Pindar's extant odes glance at the long technical development of Greek lyric poetry before his time, and at the various elements of art which the lyrist was required to temper into a harmonious whole (see, *e.g.*, *Ol.* iii. 8, vi. 91, xiii. 18, xiv. 15; *Pyth.* xii. 23, &c.). The earliest ode which can be dated (*Pyth.* x.) belongs to the twentieth year of Pindar's age (502 B.C.); the latest (*Olymp.* v.) to the seventieth (452 B.C.).[2] He visited the court of Hiero at Syracuse; Theron, the despot of Acragas, also entertained him; and his travels perhaps included Cyrene. Tradition notices the special closeness of his relations with Delphi: "He was greatly honoured by all the Greeks, because he was so beloved of Apollo that he even received a share of the offerings; and at the sacrifices the priest would cry aloud that Pindar come in to the feast of the god."[3] His wife's name was Megacleia (another account says Timoxena, but this may have been a second wife), and he had a son named Daiphantus and two daughters, Eumetis and Protomache. He is said to have died at Argos, at the age of seventy-nine, in 443 B.C.

Among the Greeks of his own and later times Pindar was pre-eminently distinguished for his piety towards the gods. He tells us that, "near to the vestibule" of his house (*Pyth.* iii. 78), choruses of maidens used to dance and sing by night in praise of the Mother of the Gods (Cybele) and Pan—deities peculiarly associated with the Phrygian music of the flute, in which other members of Pindar's family besides the poet himself are said to have excelled. A statue and shrine of Cybele, which he dedicated at Thebes, were the work of the Theban artists, Aristomedes and Socrates. He also dedicated at Thebes a statue to Hermes Agoraios, and another, by Calamis, to Zeus Ammon. The latter god claimed his especial veneration because Cyrene, one of the homes of his Aegid ancestry, stood "where Zeus Ammon hath his seat," *i.e.* near the oasis and temple

[1] The references are to the edition of Pindar by C. A. M. Fennell (1893–1899), and the fourth edition of Bergk's *Poetae lyrici graeci.*

[2] According to others, his latest poem is the eighth Pythian ode, 450 or 446.

[3] Πινδάρου γένος, in ed. Ald.

(*Pyth*. iv. 16). The author of one of the Greek lives of Pindar says that, "when Pausanias the king of the Lacedaemonians was burning Thebes, some one wrote on Pindar's house, 'Burn not the house of Pindar the poet'; and thus it alone escaped destruction." This incident, of which the occasion is not further defined, has been regarded as a later invention.[1] Better attested, at least, is the similar clemency of Alexander the Great, when he sacked Thebes one hundred and eight years after the traditional date of Pindar's death (335 B.C.). He spared only (1) the Cadmeia, or citadel, of Thebes (thenceforth to be occupied by a Macedonian garrison); (2) the temples and holy places; and (3) Pindar's house. While the inhabitants were sold into slavery, exception was made only of (1) priests and priestesses; (2) persons who had been connected by private *ξενία* with Philip or Alexander, or by public *ξενία* with the Macedonians; (3) Pindar's descendants. It is probable enough, as Dio Chrysostom suggests (ii. 33), that Alexander was partly moved by personal gratitude to a poet who had celebrated his ancestor Alexander I. of Macedon. But he must have been also, or chiefly, influenced by the sacredness which in the eyes of all Hellenes surrounded Pindar's memory, not only as that of a great national poet, but also as that of a man who had stood in a specially close relation to the gods, and, above all, to the Delphian Apollo.[2] Upwards of six hundred years after Pindar's death the traveller Pausanias saw an iron chair which was preserved among the most precious treasures of the temple in the sanctuary at Delphi. It was the chair, he was told, "in which Pindar used to sit, whenever he came to Delphi, and to chant those of his songs which pertain to Apollo" (x. 24, 5).

During the second half of Pindar's life, Athens was rising to that supremacy in literature and art which was to prove more lasting than her political primacy. Pindar did not live to see the Parthenon, or to witness the mature triumphs of Sophocles; but he knew the sculpture of Calamis, and he may have known the masterpieces of Aeschylus. It is interesting to note the feeling of this great Theban poet, who stands midway between Homeric epos and Athenian drama, towards the Athens of which Thebes was so often the bitterest foe, but with which he himself had so large a measure of spiritual kinship. A few words remain from a dithyramb in which he paid a glowing tribute to those "sons of Athens" who "laid the shining foundations of freedom" (*παῖδες Ἀθαναίων ἐβάλοντο φαεννὰν κρηπῖδ' ἐλευθερίας*, *fr*. 55, Bergk[4], 77), while Athens itself is thus invoked: *ὦ ταὶ λιπαραὶ καὶ ἰοστέφανοι καὶ ἀοίδιμοι, Ἑλλάδος ἔρεισμα, κλειναὶ Ἀθᾶναι, δαιμόνιον πτολίεθρον* (*fr*. 54, Bergk[4], 76). Isocrates, writing in 353 B.C., states that the phrase Ἑλλάδος ἔρεισμα, "stay of Hellas," so greatly gratified the Athenians that they conferred on Pindar the high distinction of *προξενία* (*i.e.* appointed him honorary consul, as it were—for Athens at Thebes), besides presenting him with a large sum of money (*Antidosis*, 166). One of the letters of the pseudo-Aeschines (*Ep*. iv.) gives an improbable turn to the story by saying that the Thebans had fined Pindar for his praise of Athens, and that the Athenians repaid him twice the sum.[3] The notice preserved by Isocrates—less than one hundred years after Pindar's death—is good warrant for the belief that Pindar had received some exceptional honours from Athens. Pausanias saw a statue of Pindar at Athens, near the temple of Ares (i. 8, 4). Besides the fragment just mentioned, several passages in Pindar's extant odes bespeak his love for Athens. Its name is almost always joined by him with some epithet of praise or reverence. In alluding to the great battles of the Persian wars, while he gives the glory of Plataea to the Spartans, he assigns that of Salamis to the Athenians (*Pyth*. i. 76). In celebrating (*Pyth*. vii.) the Pythian victory of the Athenian Megacles, he begins thus: "Fairest of preludes is the renown of Athens for the mighty race of the Alcmaeonidae. What home, or what house, could I call mine by a name that should sound more glorious for Hellas to hear?" Referring to the fact that an Aeginetan victor in the games had been trained by an Athenian, he says (*Nem*. v. 49) "meet it is that a shaper of athletes should come from Athens"—and recollecting how often Pindar compares the poet's efforts to the athlete's, we may well believe that he was thinking of his own early training at Athens.

Works.

Pindar's versatility as a lyric poet is one of the characteristics remarked by Horace (*Odes*, iv. 2), and is proved by the fragments, though the poems which have come down entire represent only one class of compositions—the *Epinicia*, or odes of victory, commemorating successes in the great games. The lyric types to which the fragments belong, though it cannot be assumed that the list is complete, are at least numerous and varied.

Fragments.

(1) Ὕμνοι, *Hymns* to deities—as to Zeus Ammon, to Persephone, to Fortune. The fragmentary ὕμνος entitled Θηβαίοις seems to have celebrated the deities of Thebes. (2) Παιᾶνες, *Paeans*, expressing prayer or praise for the help of a protecting god, especially Apollo, Artemis or Zeus. (3) Διθύραμβοι, *Dithyrambs*, odes of a lofty and impassioned strain, sung by choruses in honour of Dionysus (cf. Pind. *Ol*. xiii. 18, *ταὶ Διωνύσου πόθεν ἐξέφανεν σὺν βοηλάτᾳ Χάριτες διθυράμβῳ*—where Pindar alludes to the choral form given to the dithyramb, *c*. 600 B.C., by Arion—*βοηλάτης*, "ox-driving," perhaps meaning "winning an ox as prize"). (4) Προσόδια, *Processional Songs*, choral chants for worshippers approaching a shrine. One was written by Pindar for the Delians, another for the Aeginetans. (5) Παρθένια, *Choral Songs for Maidens*. The reference in *Pyth*. iii. 78 to maidens worshipping Cybele and Pan near the poet's house is illustrated by the fact that one of these Παρθένια invoked "Pan, lord of Arcadia, attendant of the Great Mother, watcher of her awful shrine" (*fr*. 72, Bergk[4], 95). (6) Ὑπορχήματα, *Choral Dance-Songs*, adapted to a lively movement, used from an early date in the cult of Apollo, and afterwards in that of other gods, especially Dionysus. To this class belongs one of the finest fragments (84, Bergk[4], 107), written for the Thebans in connexion with propitiatory rites after an eclipse of the sun, probably that of the 30th of April 463 B.C. (7) Ἐγκώμια, *Songs of Praise* (for men, while ὕμνοι were for gods), to be sung by a *κῶμος* or festal company. In strictness *ἐγκώμιον* was the genus of which *ἐπινίκιον* was a species; but the latter is more conveniently treated as a distinct kind. Pindar wrote encomia for Theron, despot of Acragas, and for Alexander I. (son of Amyntas), king of Macedon. (8) Σκόλια, *Festal Songs*. The usual sense of *σκόλιον* is a drinking-song, taken up by one guest after another at a banquet. But Pindar's *σκόλια* were choral and antistrophic. One was to be sung at Corinth by a chorus of the *ἱερόδουλοι* attached to the temple of Aphrodite Ourania, when a certain Xenophon offered sacrifice before going to compete at Olympia. Another brilliant fragment, for Theoxenus of Tenedos, has an erotic character. (9) Θρῆνοι, *Dirges*, to be sung with choral dance and the music of the flute, either at the burial of the dead or in commemorative rituals. Some of the most beautiful fragments belong to this class (106–110, Bergk[4], 129–133). One of the smaller fragments (114, Bergk[4], 137)—in memory of an Athenian who had been initiated into the Eleusinian mysteries (*ἰδὼν κεῖνα*)—has been conjecturally referred to the Θρῆνος which Pindar is said to have written (*schol. Pyth*. vii. 18) for Hippocrates, the grandfather of Pericles. A number of small fragments, which cannot be certainly classified, are usually given as *ἐξ ἀδήλων εἰδῶν*, "of uncertain class." On comparing the above list with Horace, *Odes*, iv. 2, it will be seen that he alludes to No. 3 (*dithyrambos*); to Nos. 1, 2, and 7 (*seu deos regesve canit*); and to No. 9 (*flebili sponsae juvenemve raptum Plorat*)—as well as to the extant *Epinicia* (*sive quos Elea domum reducit Palma caelestes*).

The Epinicia.—The *ἐπινίκια* (*sc. μέλη*), or *ἐπινίκιοι* (*sc. ὕμνοι*), "Odes of Victory," form a collection of forty-four odes, traditionally divided into four books, answering to the four great festivals: (1) Ὀλυμπιονῖκαι (*sc. ὕμνοι*): fourteen odes for winners of the wild olive-wreath in the Olympian games, held at Olympia in honour of Zeus once in four years; (2) Πυθιονῖκαι: twelve odes for winners of the laurel-wreath in the Pythian games held at Delphi in honour of Apollo, once in four years, the third of each Olympiad; (3) Νεμεονῖκαι: eleven odes for winners of the pine-wreath in the Nemean games, held at Nemea, in honour of Zeus, once in two years, the second and fourth of each Olympiad; and (4) Ἰσθμιονῖκαι: seven odes for winners of the parsley wreath in the Isthmian games, held at the Isthmus

[1] A. Schäfer, *Demosthenes und seine Zeit*, iii. 119.

[2] It will be remarked that history requires us to modify the statement in Milton's famous lines:—

"The great Emathian conqueror bade spare
The house of Pindarus, when *temple* and tower
Went to the ground."

Indeed, the point of the incident depends much on the fact that the temples and Pindar's house were classed together for exemption.

[3] Compare Jebb, *Attic Orators*, ii. 143.

of Corinth, in honour of Poseidon, once in two years, the first and third of each Olympiad. The Greek way of citing an ode is by the nomin. *plur.* followed by the numeral, *e.g.* "the ninth Olympian" is 'Ολυμπιονῖκαι θ'. The chronological range of the collection (so far as ascertainable) is from 502 B.C. (*Pyth.* x. to 452 B.C. (*Ol.* v.). With respect to the native places of the victors, the geographical distribution is as follows: for the mainland of Greece proper, 13 odes; for Aegina, 11; for Sicily, 15; for the Epizephyrian Locrians (southern Italy), 2; for Cyrene (Africa), 3.

The general characteristics of the odes may be briefly considered under the following heads: (1) language; (2) treatment of theme; (3) sentiment—religious, moral and political; (4) relation to contemporary art.

1. The diction of Pindar is distinct in character from that of every other Greek poet, being almost everywhere marked by the greatest imaginative boldness. Thus (*a*) metaphor is used even for the expression of common ideas, or the translation of familiar phrases, as when a cloak is called (*Ol.* ix. 97) "a warm remedy for winds." (*b*) Images for the highest excellence are drawn from the farthest limits of travel or navigation, or from the fairest of natural objects; as when the superlative hospitality of a man who kept open house all the year round is described by saying, "far as to Phasis was his voyage in summer days, and in winter to the shores of Nile" (*Isthm.* ii. 41); or when Olympia, the "crown" or "flower" of festivals, is said to be excellent as water, bright as gold, brilliant as the noonday sun (*Ol.* i. *ad init.*). This trait might be called *the Pindaric imagery of the superlative.* (*c*) Poetical inversion of ordinary phrase is frequent; as, instead of, "he struck fear into the beasts," "he gave the beasts to fear" (*Pyth.* v. 56). (*d*) The efforts of the poet's genius are represented under an extraordinary number of similitudes, borrowed from javelin-throwing, chariot-driving, leaping, rowing, sailing, ploughing, building, shooting with the bow, sharpening a knife on a whetstone, mixing wine in a bowl, and many more. (*e*) Homely images, from common life, are not rare; as from account-keeping, usury, sending merchandise over sea, the σκυτάλη or secret despatch, &c. And we have such homely proverbs as, "he hath his foot in this shoe," *i.e.* stands in this case (*Ol.* vi. 8). (*f*) The natural order of words in a sentence is often boldly deranged, while, on the other hand, the syntax is seldom difficult. (*g*) Words not found except in Pindar are numerous, many of these being compounds which (like ἐναρίμβροτος, καταφυλλοροεῖν, &c.) suited the dactylic metres in their Pindaric combinations. Horace was right in speaking of Pindar's "nova verba," though they were not confined to the "audaces dithyrambi."

2. The actual victory which gave occasion for the ode is seldom treated at length or in detail—which, indeed, only exceptional incidents could justify. Pindar's method is to take some heroic myth, or group of myths, connected with the victor's city or family, and, after a brief prelude, to enter on this, returning at the close, as a rule, to the subject of the victor's merit or good fortune, and interspersing the whole with moral comment. Thus the fourth Pythian is for Arcesilaus, king of Cyrene, which was said to have been founded by men of Thera, descendants of one of Jason's comrades. Using this link, Pindar introduces his splendid narrative of the Argonauts. Many odes, again, contain shorter mythical episodes—as the birth of Iamus (*Ol.* vi.), or the vision of Bellerophon (*Ol.* xiii.)—which form small pictures of masterly finish and beauty. Particular notice is due to the skill with which Pindar often manages the return from a mythical digression to his immediate theme. It is bold and swift, yet is not felt as harshly abrupt—justifying his own phrase at one such turn—καί τινα οἶμον ἴσαμι βραχύν (*Pyth.* iv. 247). It has been thought that, in the parenthesis about the Amazons' shields (*quibus Mos unde deductus . . . quaerere distuli, Odes* iv. 4, 18), Horace was imitating a Pindaric transition; if so, he has illustrated his own observation as to the peril of imitating the Theban poet.

3. *a.* The religious feeling of Pindar is strongly marked in the odes. "From the gods are all means of human excellence." He will not believe that the gods, when they dined with Tantalus, ate his son Pelops; rather Poseidon carried off the youth to Olympus. That is, his reason for rejecting a scandalous story about the gods is purely religious, as distinct from moral; it shocks his conception of the divine dignity. With regard to oracles, he inculcates precisely such a view as would have been most acceptable to the Delphic priesthood, viz. that the gods do illumine their prophets, but that human wit can foresee nothing which the gods do not choose to reveal. A mystical doctrine of the soul's destiny after death appears in some passages (as *Ol.* ii. 66 seq.). Pindar was familiar with the idea of metempsychosis (cf. ibid. 68), but the attempt to trace Pythagoreanism in some phrases (*Pyth.* ii. 34, iii. 74) appears unsafe. The belief in a fully conscious existence for the soul in a future state, determined by the character of the earthly life, entered into the teaching of the Eleusinian and other mysteries. Comparing the fragment of the Θρῆνος (114, Bergk[4], 137), we may probably regard the mystic or esoteric element in Pindar's theology as due to such a source.

b. The moral sentiment pervading Pindar's odes rests on a constant recognition of the limits imposed by the divine will on human effort, combined with strenuous exhortation that each man should strive to reach the limit allowed in his own case. Native temperament (φυή) is the grand source of all human excellence (ἀρετή), while such excellences as can be acquired by study (διδακταὶ ἀρεταί, *Ol.* ix. 100) are of relatively small scope—the sentiment, we may remark, of one whose thoughts were habitually conversant with the native qualities of a poet on the one hand and of an athlete on the other. The elements of ὑγίεις ὄλβος—"sane happiness," such as has least reason to dread the jealousy of the gods—are substance sufficing for daily wants and good repute (εὐλογία). He who has these should not "seek to be a god." "Wealth set with virtues" (πλοῦτος ἀρεταῖς δεδαιδαλμένος), as gold with precious gems, is the most fortunate lot, because it affords the amplest opportunities for honourable activity. Pindar does not rise above the ethical standard of an age which said, "love thy friend and hate thy foe" (cf. *Pyth.* ii. 83; *Isthm.* iii. 65). But in one sense he has a moral elevation which is distinctively his own; he is the glowing prophet of generous emulation and of reverent self-control.

c. The political sentiments of the Theban poet are suggested by *Pyth.* xi. 52; "In polities I find the middle state crowned with more enduring good; therefore praise I not the despot's portion; those virtues move my zeal which serve the folk." If in *Pyth.* ii. 87, a democracy is described as ὁ λάβρος στρατός, "the raging crowd," it is to be noted that the ode is for Hiero of Syracuse, and that the phrase clearly refers to the violence of those democratic revolutions which, in the early part of the 5th century B.C., more than once convulsed Sicilian cities. At Thebes, after the Persian wars, a "constitutional oligarchy" (ὀλιγαρχία ἰσόνομος, Thuc. iii. 62) had replaced the narrower and less temperate oligarchy of former days (δυναστεία οὐ μετὰ νόμων); and in this we may probably recognize the phase of Greek political life most congenial to Pindar. He speaks of a king's lot as unique in its opportunities (*Ol.* i. 113); he sketches the character of an ideal king (*Pyth.* iii. 71); but nothing in his poetry implies liking for the τυραννίς as a form of government. Towards the Greek princes of Sicily and Cyrene his tone is ever one of manly independence; he speaks as a Greek citizen whose lineage places him on a level with the proudest of the Dorian race, and whose office invests him with an almost sacred dignity. In regard to the politics of Hellas at large, Pindar makes us feel the new sense of leisure for quiet pursuits and civilizing arts which came after the Persian wars. He honours "Tranquillity, the friend of cities" ('Ασυχία φιλόπολις, *Ol.* iv. 16). The epic poet sang of wars; Pindar celebrates the "rivalries of peace."

4. Pindar's genius was boldly original; at the same time he was an exquisite artist. "Mine be it to invent new strains, mine the skill to hold my course in the chariot of the Muses; and may courage go with me, and power of ample grasp" (*Ol.*

ix. 80). Here we see the exulting sense of inborn strength; in many other places we perceive the feeling of conscious art—as in the phrase δαιδάλλειν, so apt for his method of inlaying an ode with mythical subjects, or when he compares the opening of a song to the front of a stately building (*Ol.* vi. 3). Pindar's sympathy with external nature was deeper and keener than is often discernible in the poetry of his age. It appears, for example, in his welcome of the season when "the chamber of the hours is opened, and delicate plants perceive the fragrant spring" (*fr.* 53, Bergk[4], 75); in the passage where Jason invokes "the rushing strength of waves and winds, and the nights, and the paths of the deep" (*Pyth.* iv. 195); in the lines on the eclipse of the sun (*fr.* 84, Bergk,[4] 107); and in the picture of the eruption, when Etna, "pillar of the sky, nurse of keen snow all the year," sends forth "pure springs of fire unapproachable" (*Pyth.* i. 20). The poet's feeling for colour is often noticeable—as in the beautiful story of the birth of Iamus—when Evadne lays aside her silver pitcher and her girdle of scarlet web; the babe is found, "its delicate body steeped in the golden and deep purple rays of pansies" (*Ol.* vi. 55).

The spirit of art, in every form, is represented for Pindar by χάρις—"the source of all delights to mortals" (*Ol.* i. 30)—or by the personified Charites (Graces). The Charites were often represented as young maidens, decking themselves with early flowers—the rose, in particular, being sacred to them as well as to Aphrodite. In Pindar's mind, as in the old Greek conception from which the worship of the Charites sprang, the instinct of beautiful art was inseparable from the sense of natural beauty. The period from 500 to 460 B.C., to which most of Pindar's extant odes belong, marked a stage in the development of Greek sculpture. The schools of Argos, Sicyon and Aegina were effecting a transition from archaic types to the art which was afterwards matured in the age of Pheidias. Olympia forms the central link between Pindar's poetry and Greek sculpture. From about 560 B.C. onwards sculpture had been applied to the commemoration of athletes, chiefly at Olympia. In a striking passage (*Nem.* v. *ad. init.*) Pindar recognizes sculpture and poetry as sister arts employed in the commemoration of the athlete, and contrasts the merely local effect of the statue with the wide diffusion of the poem. "No sculptor I, to fashion images that shall stand idly on one pedestal for aye; no, go thou forth from Aegina, sweet song of mine, on every freighted ship, on each light bark." Many particular subjects were common to Pindar and contemporary sculpture. Thus (1) the sculptures on the east pediment of the temple at Aegina represented Heracles coming to seek the aid of Telamon against Troy—a theme brilliantly treated by Pindar in the fifth Isthmian; (2) Hiero's victory in the chariot-race was commemorated at Olympia by the joint work of the sculptors Onatas and Calamis; (3) the Gigantomachia, (4) the wedding of Heracles and Hebe, (5) the war of the Centaurs with the Lapithae, and (6) a contest between Heracles and Apollo, are instances of mythical material treated alike by the poet and by sculptors of his day. The contemporary improvements in town architecture, introducing spacious and well-paved streets, such as the σκυρωτὴ ὁδός at Cyrene (*Pyth.* v. 87), suggests his frequent comparison of the paths of song to broad and stately causeways (πλατεῖαι πρόσοδοι—ἑκατόμπεδοι κέλευθοι, *Nem.* vi. 47; *Isthm.* v. 22). A song is likened to cunning work which blends gold, ivory and coral (*Nem.* vii. 78). Pindar's feeling that poetry, though essentially a divine gift, has a technical side (σοφία), and that on this side it has had an historical development like that of other arts, is forcibly illustrated by his reference to the inventions (σοφίσματα) for which Corinth had early been famous. He instances (1) the development of the dithyramb, (2) certain improvements in the harnessing and driving of horses, and (3) the addition of the pediment to temples (*Ol.* xiii. 21).

Sculpture.

In the development of Greek lyric poetry two periods are broadly distinguished. During the first, from about 600 to 500 B.C., lyric poetry is local or tribal—as Alcaeus and Sappho write for Lesbians, Alcman and Stesichorus for Dorians. During the second period, which takes its rise in the sense of Hellenic unity created by the Persian wars, the lyric poet addresses all Greece. Pindar and Simonides are the great representatives of this second period, to which Bacchylides, the nephew of Simonides, also belongs. These, with a few minor poets, are classed by German writers as *die universalen Meliker.* The Greeks usually spoke, not of "lyric," but of "melic" poetry (*i.e.* meant to be sung, and not, like the epic, recited); and "universal melic" is lyric poetry addressed to all Greece. But Pindar is more than the chief extant lyrist. Epic, lyric and dramatic poetry succeeded each other in Greek literature by a natural development. Each of them was the spontaneous utterance of the age which brought it forth. In Pindar we can see that phase of the Greek mind which produced Homeric epos passing over into the phase which produced Athenian drama. His spirit is often thoroughly dramatic—witness such scenes as the interview between Jason and Pelias (*Pyth.* iv.), the meeting of Apollo and Chiron (*Pyth.* ix.), the episode of Castor and Polydeuces (*Nem.* x.), the entertainment of Heracles by Telamon (*Isthm.* v.). Epic narrative alone was no longer enough for the men who had known that great trilogy of national life, the Persian invasions; they longed to see the heroes moving and to hear them speaking. The poet of Olympia, accustomed to see beautiful forms in vivid action or vivid art, was well fitted to be the lyric interpreter of the new dramatic impulse. Pindar has more of the Homeric spirit than any Greek lyric poet known to us. On the other side, he has a genuine, if less evident, kinship with Aeschylus and Sophocles. Pindar's work, like Olympia itself, illustrates the spiritual unity of Greek art.

The fact that certain glosses and lacunae are common to all our MSS. of Pindar make it probable that these MSS. are derived from a common archetype. Now the older scholia on Pindar, which appear to have been compiled mainly from the commentaries of Didymns (*c.* 15 B.C.), somctimes presuppose a purer text than ours. But the compiler of these older scholia lived after Herodian (A.D. 160). The archetype of onr MSS., then, cannot have been older than the end of tho 2nd century. Our MSS. fall into two general classes: (1) the older, representing a text which, though often corrupt, is comparatively free from interpolations; (2) the later, which exhibit tho traces of a Byzantine recension, in other words, of lawless conjecture, down to the 14th or 15th century. To the first class belong Parisinus 7, breaking off in *Pyth.* v.; Ambrosianus 1, which has only *Ol.* i.–xii.; Mediceus 2; and Vaticanus 2—the two last-named being of the highest value. The editio princeps is the Aldine (Venice, 1513). A modern study of Pindar may be almost said to have begun with C. G. Heyne's edition (1773). Hermann did much to advance Pindaric criticism. But August Böckh (1811–1821), who was assisted in his commentary by L. Dissen, is justly regarded as the founder of a scientific treatment of the poet. Tho edition of Theodor Bergk (*Poetae lyrici graeci*, new ed. by O. Schröder, 1900) is marked by considerable boldness of conjecture, as that of Tycho Mommsen (1864) by a sometimes excessive adherence to MSS. A recension by W. Christ has been published in Teubner's series (2nd ed., 1896), also with Prolegomena and commentary (1896); and by O. Schröder (1908). The complete edition of J. W. Donaldson (1841) has many merits; but that of C. A. M. Fennell (1879–1883; new ed., 1893–1899) is better adapted to the needs of English students. The *Olympia* and *Pythia* have been edited by B. L. Gildersleevo (1885); the *Nemea* and *Isthmia* by J. B. Bury (1890–1892); the *Scholia* by E. Abel (1890, unfinished) and A. B. Brachmann (1903). There is a special lexicon by J. Rumpel (1883). The translation into English prose by Ernest Myers (2nd ed., 1883) is excellent; verse translation by T. C. Baring (1875), and of the *Olympian Odes* by Cyril Mayno (1906). Pindar's metres have been analysed by J. H. H. Schmidt, in *Die Kunstformen der griechischen Poesie* (Leipzig, 1868–1872). On Pindar generally, see monographs by A. F. Villemain (1859), L. Schmidt (1862), G. Lübbert (1882), A. Croiset (1880), W. Christ, *Geschichte der griechischen Litteratur* (1898); and the little volume by F. D. Morice in Blackwood's *Ancient Classics for English Readers*. Exhaustive bibliographical information on the earlier literature will be found in Engelmann, *Scriptores graeci* (1881); see also L. Bornemann, in Bursian's *Jahresbericht*, (cxvi. 1904), with special reference to chronological questions and *Pythia*, i., ii., iii. Some considerable fragments of the paeans were discovered in 1906 by B. P. Grenfell and A. S. Hunt (see *Oxyrhynchus papyri*, pt. v. pp. 24–81); some critical notes will be found in *Classical Review*, Feb. 1908 (A. E. Housman).

(R. C. J.; X.)

PINDARICS, the name by which was known a class of loose and irregular odes greatly in fashion in England during the close

of the 17th and the beginning of the 18th century. The invention is due to Abraham Cowley, who, probably in Paris—"a place where he had no other books to direct him"—and perhaps in 1650, found a text of Pindar and determined to imitate the Greek poetry in English, without having comprehended the system upon which Pindar's prosody was built up. Cowley published, however, in 1656, fifteen *Pindarique Odes*, which became the model on which countless imitators founded their pindarics. The erroneous form of these poems, which were absolutely without discipline of structure, was first exposed by Congreve, exactly half a century later, he very justly describing them as "bundles of rambling incoherent thoughts, expressed in a like parcel of irregular stanzas, which also consist of such another complication of disproportioned, uncertain and perplexed verses and rhymes." This is harsh, but it describes a pindaric with absolute justice. Cowley had not been aware that "there is nothing more regular than the *Odes* of Pindar," and that his poems were constructed in harmony with rigid prosodical laws in strophe, antistrophe and epode; "the liberty which Pindar took in his numbers, which has been so much misunderstood and misapplied by his pretended imitators, was only in varying the stanzas in different odes; but in each particular ode they are ever correspondent one to another in their turns, and according to the order of the ode." These excellent critical remarks were made by Congreve in his *Discourse on the Pindarique Ode* of 1706, and from that date forward the use of pindarics ceased to be so lax and frantic as it had been during the previous fifty years. The time had now passed in which such a critic as Sprat could praise "this loose and unconfined measure" as having "all the grace and harmony of the most confined." It began to be felt that the English pindaric was a blunder founded upon a misconception. If we examine Cowley's "Resurrection," which was considered in the 17th century to be a model of the style, and "truly pindarical," we find it to be a shapeless poem of 64 lines, arbitrarily divided, not into strophes, but into four stanzas of unequal volume and structure; the lines which form these stanzas are of lengths varying from three feet to seven feet, with rhymes repeated in wilful disorder, the whole forming a mere vague caricature of Pindar's brilliant odes. The very laxity of these pindarics attracted the poets of the unlyrical close of the 17th century, and they served the purpose not only of Dryden and Pope, but of a score of lesser poets, among whom Oldham, Mrs Behn, Otway, Sprat, Flatman and many others were prominent. The pindaric became the almost necessary form in which to indite a poem of compliment on a birth, a wedding or a funeral. Although the vogue of these forms hardly survived the age of Anne, something of the vicious tradition of them still remained, and even in the odes of Wordsworth, Shelley and Coleridge the broken versification of Cowley's pindarics occasionally survives. Tennyson's *Ode on the Death of the Duke of Wellington* (1852) is the latest important specimen of a pindaric in English literature. (E. G.)

PINDARIS, a word of uncertain origin, applied to the irregular horsemen who accompanied the Mahratta armies in India during the 18th century when the Mughal Empire was breaking up; loosely organized under self-chosen leaders, each band was usually attached to one or other of the great Mahratta chieftains. Their special characteristic was that they received no pay, but rather purchased the privilege of plundering on their own account. The majority of them seem to have been Mahommedans: when the regular forces of the Mahrattas had been broken up in the campaigns conducted by Sir Arthur Wellesley and Lord Lake in 1802–04, the Pindaris made their headquarters in Malwa, under the tacit protection of Sindhia and Holkar. They were accustomed to assemble every year at the beginning of November, and sally forth into British territory in search of plunder. In one such raid upon the Masulipatam coast they plundered 339 villages, killing or wounding 682 persons, torturing 3600, and carrying off property worth a quarter of a million. In 1808–09 they plundered Gujarat, and in 1812 Mirzapur. In 1814 they were reckoned at 25,000 to 30,000 horsemen, half of them well armed. At last the evil became intolerable, and in 1817 the marquess of Hastings obtained the consent of the East India Company to the organized campaign, known as the Pindari War. The Pindaris were surrounded on all sides by a great army, consisting of 120,000 men and 300 guns, which converged upon them from Bengal, the Deccan and Gujarat under the supreme command of Lord Hastings in person. Sindhia was overawed and forced to sign the treaty of Gwalior, consenting to aid in the extirpation of the Pindaris, whom he had hitherto protected. The Peshwa at Poona, the Bhonsla raja at Nagpur, and the army of the infant Holkar each took up arms, but were separately defeated. The Pindaris themselves offered little opposition. Amir Khan, by far their most powerful leader, accepted the conditions offered to him; and his descendant is now Nawab of the state of Tonk in Rajputana. The rest surrendered or were hunted down, the fate of Chitu, one of the most notorious, being to perish in a tiger's den. These military operations were followed by the pacification of Central India under the administration of Sir John Malcolm.

See J. Grant Duff, *History of the Mahrattas* (1826); and Major Ross of Bladensburg, *Marquess of Hastings* (Rulers of India Series) (1893).

PIND DADAN KHAN, a town of British India, in the Jhelum district of the Punjab, situated near the right bank of the river Jhelum, on the Sind-Sagar branch of the North-Western railway. Pop. (1901), 13,770. It is an important centre of trade, and its manufactures include boats, brass-ware, pottery, embroidered scarves and riding-whips.

PINDUS, the ancient name of the rugged group of mountains which separates Thessaly from Epirus, and branches south in various directions. The geographical name is sometimes extended over all these branches, and so reaches from Aetolia to the Gulf of Lamia. The northern part of the ridge was known as Lacmon. There is no modern name covering the whole range, but its different parts have separate names. Several of them attain a height of 7000 ft. or more.

PINE (Lat. *Pinus*, Gr. πίτυς), a name given by the ancients to some of the resinous cone-bearing trees to which it is now applied, and, as limited by modern botanists, the designation of a large genus of true conifers, differing from the firs in their hard woody cone-scales being thickened at the apex, and in their slender needle-shaped leaves growing from a membranous sheath, either in pairs or from three to five together—each tuft representing an abortive branch, springing from the axil of a partially deciduous scale-leaf, the base of which remains closely adherent to the stem. The numerous male catkins are generally arranged in dense whorls around the bases of the young shoots; the anther-scales, surmounted by a crest-like appendage, shed their abundant pollen by longitudinal slits; the two ovules at the base of the inner side of each fertile cone-scale develop into a pair of winged seeds, which drop from the opening scales when mature—as in the allied genera.

The pines are widely distributed over the north temperate zone, in the southern portions chiefly confined to the mountains, along which, in Central America, a few are found within the tropic; in more northern regions they frequently form extensive forests, sometimes hardly mingled with other trees. Their soft, straight-grained, resinous and often durable wood gives to many kinds a high economic value, and some are among the most esteemed of timber trees.

Of the two-leaved species, *P. sylvestris*, the pine of northern Europe, may be taken as a type. When growing in perfection it is one of the finest of the group, and perhaps the most picturesque of forest trees; attaining a height of from 70 to 120 ft., it is of conical growth when young, but in maturity acquires a spreading cedar or mushroom-like top, with a straight trunk of from 2 to 4 ft. in diameter at the base, and gnarled twisted boughs, densely clothed at the extremities with glaucous green foliage, which contrasts strongly with the fiery red-brown bark. The leaves are rather short, curved, and often twisted; the male catkins, in dense cylindrical whorls, fill the air of the forest with their sulphur-like pollen in May or June, and fecundate the purple female flowers, which, at first sessile and erect, then

ix. 80). Here we see the exulting sense of inborn strength; in many other places we perceive the feeling of conscious art—as in the phrase δαιδάλλειν, so apt for his method of inlaying an ode with mythical subjects, or when he compares the opening of a song to the front of a stately building (*Ol.* vi. 3). Pindar's sympathy with external nature was deeper and keener than is often discernible in the poetry of his age. It appears, for example, in his welcome of the season when "the chamber of the hours is opened, and delicate plants perceive the fragrant spring" (*fr.* 53, Bergk[4], 75); in the passage where Jason invokes "the rushing strength of waves and winds, and the nights, and the paths of the deep" (*Pyth.* iv. 195); in the lines on the eclipse of the sun (*fr.* 84, Bergk,[4] 107); and in the picture of the eruption, when Etna, "pillar of the sky, nurse of keen snow all the year," sends forth "pure springs of fire unapproachable" (*Pyth.* i. 20). The poet's feeling for colour is often noticeable—as in the beautiful story of the birth of Iamus—when Evadne lays aside her silver pitcher and her girdle of scarlet web; the babe is found, "its delicate body steeped in the golden and deep purple rays of pansies" (*Ol.* vi. 55).

The spirit of art, in every form, is represented for Pindar by χάρις—"the source of all delights to mortals" (*Ol.* i. 30)—or by the personified Charites (Graces). The Charites were often represented as young maidens, decking themselves with early flowers—the rose, in particular, being sacred to them as well as to Aphrodite. In Pindar's mind, as in the old Greek conception from which the worship of the Charites sprang, the instinct of beautiful art was inseparable from the sense of natural beauty.

Sculpture.

The period from 500 to 460 B.C., to which most of Pindar's extant odes belong, marked a stage in the development of Greek sculpture. The schools of Argos, Sicyon and Aegina were effecting a transition from archaic types to the art which was afterwards matured in the age of Pheidias. Olympia forms the central link between Pindar's poetry and Greek sculpture. From about 560 B.C. onwards sculpture had been applied to the commemoration of athletes, chiefly at Olympia. In a striking passage (*Nem.* v. *ad. init.*) Pindar recognizes sculpture and poetry as sister arts employed in the commemoration of the athlete, and contrasts the merely local effect of the statue with the wide diffusion of the poem. "No sculptor I, to fashion images that shall stand idly on one pedestal for aye; no, go thou forth from Aegina, sweet song of mine, on every freighted ship, on each light bark." Many particular subjects were common to Pindar and contemporary sculpture. Thus (1) the sculptures on the east pediment of the temple at Aegina represented Heracles coming to seek the aid of Telamon against Troy—a theme brilliantly treated by Pindar in the fifth Isthmian; (2) Hiero's victory in the chariot-race was commemorated at Olympia by the joint work of the sculptors Onatas and Calamis; (3) the Gigantomachia, (4) the wedding of Heracles and Hebe, (5) the war of the Centaurs with the Lapithae, and (6) a contest between Heracles and Apollo, are instances of mythical material treated alike by the poet and by sculptors of his day. The contemporary improvements in town architecture, introducing spacious and well-paved streets, such as the σκυρωτὴ ὁδός at Cyrene (*Pyth.* v. 87), suggests his frequent comparison of the paths of song to broad and stately causeways (πλατεῖαι πρόσοδοι—ἑκατόμπεδοι κέλευθοι, *Nem.* vi. 47; *Isthm.* v. 22). A song is likened to cunning work which blends gold, ivory and coral (*Nem.* vii. 78). Pindar's feeling that poetry, though essentially a divine gift, has a technical side (σοφία), and that on this side it has had an historical development like that of other arts, is forcibly illustrated by his reference to the inventions (σοφίσματα) for which Corinth had early been famous. He instances (1) the development of the dithyramb, (2) certain improvements in the harnessing and driving of horses, and (3) the addition of the pediment to temples (*Ol.* xiii. 21).

In the development of Greek lyric poetry two periods are broadly distinguished. During the first, from about 600 to 500 B.C., lyric poetry is local or tribal—as Alcaeus and Sappho write for Lesbians, Alcman and Stesichorus for Dorians. During the second period, which takes its rise in the sense of Hellenic unity created by the Persian wars, the lyric poet addresses all Greece. Pindar and Simonides are the great representatives of this second period, to which Bacchylides, the nephew of Simonides, also belongs. These, with a few minor poets, are classed by German writers as *die universalen Meliker*. The Greeks usually spoke, not of "lyric," but of "melic" poetry (*i.e.* meant to be sung, and not, like the epic, recited); and "universal melic" is lyric poetry addressed to all Greece. But Pindar is more than the chief extant lyrist. Epic, lyric and dramatic poetry succeeded each other in Greek literature by a natural development. Each of them was the spontaneous utterance of the age which brought it forth. In Pindar we can see that phase of the Greek mind which produced Homeric epos passing over into the phase which produced Athenian drama. His spirit is often thoroughly dramatic—witness such scenes as the interview between Jason and Pelias (*Pyth.* iv.), the meeting of Apollo and Chiron (*Pyth.* ix.), the episode of Castor and Polydeuces (*Nem.* x.), the entertainment of Heracles by Telamon (*Isthm.* v.). Epic narrative alone was no longer enough for the men who had known that great trilogy of national life, the Persian invasions; they longed to see the heroes moving and to hear them speaking. The poet of Olympia, accustomed to see beautiful forms in vivid action or vivid art, was well fitted to be the lyric interpreter of the new dramatic impulse. Pindar has more of the Homeric spirit than any Greek lyric poet known to us. On the other side, he has a genuine, if less evident, kinship with Aeschylus and Sophocles. Pindar's work, like Olympia itself, illustrates the spiritual unity of Greek art.

The fact that certain glosses and lacunae are common to all our MSS. of Pindar make it probable that these MSS. are derived from a common archetype. Now the older scholia on Pindar, which appear to have been compiled mainly from the commentaries of Didymus (*c.* 15 B.C.), sometimes presuppose a purer text than ours. But the compiler of these older scholia lived after Herodian (A.D. 160). The archetype of our MSS., then, cannot have been older than the end of the 2nd century. Our MSS. fall into two general classes: (1) the older, representing a text which, though often corrupt, is comparatively free from interpolations; (2) the later, which exhibit the traces of a Byzantine recension, in other words, of lawless conjecture, down to the 14th or 15th century. To the first class belong Parisinus 7, breaking off in *Pyth.* v.; Ambrosianus 1, which has only *Ol.* i.–xii.; Mediceus 2; and Vaticanus 2—the two last-named being of the highest value. The editio princeps is the Aldine (Venice, 1513). A modern study of Pindar may be almost said to have begun with C. G. Heyne's edition (1773). Hermann did much to advance Pindaric criticism. But August Böckh (1811–1821), who was assisted in his commentary by L. Dissen, is justly regarded as the founder of a scientific treatment of the poet. The edition of Theodor Bergk (*Poetae lyrici graeci*, new ed. by O. Schröder, 1900) is marked by considerable boldness of conjecture, as that of Tycho Mommsen (1864) by a sometimes excessive adherence to MSS. A recension by W. Christ has been published in Teubner's series (2nd ed., 1896), also with Prolegomena and commentary (1896); and by O. Schröder (1908). The complete edition of J. W. Donaldson (1841) has many merits; but that of C. A. M. Fennell (1879–1883; new ed., 1893–1899) is better adapted to the needs of English students. The *Olympia* and *Pythia* have been edited by B. L. Gildersleeve (1885); the *Nemea* and *Isthmia* by J. B. Bury (1890–1892); the *Scholia* by E. Abel (1890, unfinished) and A. B. Brachmann (1903). There is a special lexicon by J. Rumpel (1883). The translation into English prose by Ernest Myers (2nd ed., 1883) is excellent; verse translation by T. C. Baring (1875), and of the *Olympian Odes* by Cyril Mayne (1906). Pindar's metres have been analysed by J. H. H. Schmidt, in *Die Kunstformen der griechischen Poesie* (Leipzig, 1868–1872). On Pindar generally, see monographs by A. F. Villemain (1859), L. Schmidt (1862), G. Lübbert (1882), A. Croiset (1880), W. Christ, *Geschichte der griechischen Litteratur* (1898); and the little volume by F. D. Morice in Blackwood's *Ancient Classics for English Readers*. Exhaustive bibliographical information on the earlier literature will be found in Engelmann, *Scriptores graeci* (1881); see also L. Bornemann, in Bursian's *Jahresbericht*, (cxvi. 1904), with special reference to chronological questions and *Pythia*, i., ii., iii. Some considerable fragments of the paeans were discovered in 1906 by B. P. Grenfell and A. S. Hunt (see *Oxyrhynchus papyri*, pt. v. pp. 24–81); some critical notes will be found in *Classical Review*, Feb. 1908 (A. E. Housman).

flourishes, and the timber is always indifferent; it is usually said that the wood is best in the cold climate of its more northern habitats, but a trunk (4 ft. in diameter) grown on the sands of Surrey had heart-wood quite equal to any produced in Glenmore or Rothiemurchus. The rapidity of growth is still more variable: in Britain full maturity is attained in from seventy to one hundred and twenty years, but in Norway the trunk increases much more slowly; Schübeler states that a tree felled in the Alten district (about 70° lat.), measuring 2 ft. 10 in. in diameter without the bark, showed four hundred circles of annual growth. In Norway the tree, growing in dense forests, is generally of but moderate girth, and probably this pine nowhere reaches a greater size than in the Scottish woods; a plank from Glenmore forest measured nearly 5½ ft. across, and from 3 to 4½ ft. is not an unusual diameter for a British pine tree.

Vast numbers of Scotch firs are raised in nurseries for artificial planting; the seed is sown in the spring, being just covered with earth, and the seedlings transplanted in the second year into rows for further culture, or taken direct from the seed-bed for final planting; sometimes the seed is sown where the trees are intended to grow. A plantation of Scotch fir requires frequent and careful thinning as the young trees increase in size; but pruning should be avoided as much as possible, excepting for the removal of dead wood. Plantations in England are generally ready for final cutting in from sixty to seventy years, and many are cleared at a much earlier stage of growth. *P. sylvestris* in Britain is liable to many insect depredations: the pine-chafer, *Hylurgus piniperda*, is destructive in some places, the larva of this beetle feeding on the young succulent shoots, especially in young plantations; *Hylobius abietis*, the fir-weevil, eats away the bark, and numerous lepidopterous larvae devour the leaves; the pine-sawfly is also injurious in some seasons; the removal of all dead branches from the trees and from the ground beneath them is recommended, as most of these insects lay their eggs among the decaying bark and dead leaves. In common with other pines, *P. sylvestris* is subject to the attacks of various fungi. *Trametes radiciperda* attacks the roots and penetrates to the stem, causing rotting of the wood; the disease is difficult to eradicate, as the mycelium of the fungus travels from root to root in the soil. Rotting of the wood at the base of the trunk is also caused by *Agaricus melleus*, which spreads from root to root in the soil by means of its long purple-black, cord-like mycelial strands known as *Rhizomorpha*. Much damage is often caused by species of *Peridermium*, which often invade the cortex and cambium to such an extent as to "ring" the stem or branch, or to cause an abnormal formation of turpentine which soaks into the wood and stops the upward passage of water; this causes the parts above the diseased area to perish. In England the pine is largely employed as a "nurse" for oak trees, its conical growth when young admirably adapting it for this purpose; its dense foliage renders it valuable as a shelter tree for protecting land from the wind; it stands the sea gales better than most conifers, but will not flourish on the shore like some other species.

The pine is an important tree in the economy of the northern nations of Europe. In Scandinavia and Russia houses are chiefly constructed of its timber; and log-huts are made of the smaller trunks and lined and roofed with the bark. The inner bark is twisted into ropes, and, like that of the spruce, is kiln dried, ground up, and mixed with meal in times of scarcity; in Kamchatka it is macerated in water, then pounded, and made into a kind of substitute for bread without any admixture of flour. In recent days the fibre of the leaves has been extracted in some quantity and applied to textile purposes under the name of *waldwolle*, both in Germany and Sweden. It is prepared by boiling the needles in a solution of soda to remove the resin, which process loosens the fibre and renders its separation easy; it has some resemblance to coarse wool, and is spun and woven into blankets and garments that are said to be warm and durable; it is also used for stuffing cushions; an essential oil, obtained by a previous distillation of the leaves, has medicinal virtues attributed to it by some German practitioners.

Large quantities of turpentine are extracted from this pine in Sweden and Russia by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is scooped as it accumulates; but the product is not equal to that of the silver fir and other species. Tar is prepared largely from *P. sylvestris*; it is chiefly obtained from the roots, which, mingled with a few logs, are arranged in a conical or funnel-shaped hollow made on the steep side of a hill or bank; after filling up, the whole is covered with turf and fired at the top, when the tar exudes slowly and runs into an iron vessel placed below, from the spout of which it is conveyed into barrels. Most of the so-called Stockholm tar is thus prepared, chiefly in the province of Bothnia.

Closely allied to the Scotch pine, and perhaps to be regarded as a mere alpine form of that species, is the dwarf *P. montana* (or *P. Pumilio*), the "krummholz" or "knieholz" of the Germans—a recumbent bush, generally only a few feet high, but with long zigzag stems, that root occasionally at the knee-like bends where they rest upon the ground. The foliage much resembles that of the Scotch fir, but is shorter, denser and more rigid; the cones are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tirolese Alps, it is a favourite shelter for the chamois; the hunters call it the "latschen," from its recumbent straggling habit. Krummholz oil, valued in Germany as an outward application in rheumatism and for bruises and sprains, is distilled from the young branches, and a fragrant white resin that exudes in some quantity from the buds is used for similar purposes and as a perfume, under the name of Hungarian balsam it is sold in the towns of Germany, being probably obtained from the Carpathians.

The red pine of Canada and New England (so called from the colour of its bark), *P. resinosa*, is a tree of considerable size, sometimes attaining the dimensions of *P. sylvestris*. The somewhat glaucous leaves form dense tufts at the ends of the branches, and are 4 or 5 in. long; the ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch fir, though much employed in ship-building; according to Emerson, trunks exist in Maine 4 ft. in diameter. A sandy soil seems to suit it best, and the quality of the wood probably much depends on its place of growth. Red pines abound in Nova Scotia and Newfoundland, and the tree is rather widely distributed over the northern parts of the continent; it rarely forms extensive woods, but grows chiefly in clumps among other trees, at least in its more southern habitats. Nearly allied is *P. Banksiana*, the grey or Labrador pine, sometimes called the scrub pine from its dwarfish habit; it is the most northerly representative of the genus in America, and is chiefly remarkable for its much recurved and twisted cones, about 2 in. long. The trunks are too small to be of great economic value, but the light wood is used by the natives for their canoes.

P. Laricio, the Corsican pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 ft., with a straight trunk and branches in regular whorls, forming in large trees a pyramidal head; the slender leaves, of a dark green tint, are from 4 to 7 in. long; the cones, either in pairs or several together, project horizontally, and are of a light brown colour. This pine abounds in Corsica, and is found in more or less abundance in Spain, southern France, Greece, and many Mediterranean countries; it occurs on the higher mountains of Cyprus. The tree is of very rapid growth, but produces good timber, much used in southern dockyards, and very durable, though less strong than that of *P. sylvestris*; the heart-wood is of a brownish-tint. In southern France it has been planted with success on the drift-sands of the Bay of Biscay, though it does not bear the full force of the sea-blast as well as the pinaster. In England it grows well in sheltered situations and well-drained soils.

The black pine, *P. austriaca*, generally now regarded as a variety of *P. Laricio*, derives its name from the extreme depth of its foliage tints—the sharp, rigid, rather long leaves of a dark green hue giving a sombre aspect to the tree. The light-coloured, glossy, horizontal cones are generally in pairs, but sometimes three or four together. The tree is conical when young, but when old forms a spreading head; it often attains a large size. Southern Austria and the adjacent countries are the natural habitats of this pine; it seems to flourish best on rocky mountain sides, but in England grows well on sandy soils. The timber is valued in its native country, and is said to be durable and to stand exposure to the weather well; various resinous products are extracted from it. *P. pyrenaica* is a handsome species of pyramidal form, attaining a large size on the mountains of northern Spain, whence it extends through the Mediterranean region to Asia Minor, northern Persia and Afghanistan. The leaves are long and of a light bright green: the cones are solitary, oblong, conical and of a yellow tint. The timber is used in Spanish dockyards, but opinions vary as to its quality. In plantations its bright foliage, with the orange cones and young shoots, render it an ornamental tree, hardy in southern Britain. *P. brutia*, the Calabrian pine, is regarded as the same

species. *P. halepensis*, another Mediterranean form, is valued for its timber, which is white with a fine grain, and resinous products.

P. pinaster, the cluster pine or pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft. or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 in. long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea-sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine, which is largely obtained from the trees by a process analogous to that employed in its collection from *P. sylvestris*; the resin is yielded from May to the end of September, the cuts being renewed as the supply fails, until the tree is exhausted; the trunks are then felled and used in the manufacture of charcoal and lamp black; much tar and pitch is also obtained from these pinaster forests. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; the soft coarse wood, though perishable in the natural state, has been used for railway sleepers after saturation with creosote or preservative solutions.

P. Pinea is the stone pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nut-like seeds, which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid. The tree has been naturalized in many warm countries, even in China; in England it seldom attains any large size, as the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations 20 or 30 ft. in height; the wood, though soft and deficient in the resin that gives durability to the timber of some species, is valued by the southern carpenter and cabinetmaker for its lightness, its fineness of grain, and the ease with which it is worked.

P. mitis, the yellow pine of the northern and middle states of America, is rather allied to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of 70 ft. and upwards, though rarely more than 2 ft. in diameter at the root; the lower branches spread horizontally, the upper, converging towards the trunk, give the tree somewhat the aspect of a spruce, hence it is called in some districts the "spruce-pine." The leaves are long, slender, and of a bluish-green hue; the pendant cones are about 1½ in. long, with a slender point to each scale. The yellow pine is one of the most important timber trees of the genus; the heart-wood being very durable is largely employed in ship-building and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to Britain under the name of "New York yellow pine"; the sapwood is perishable.

The three-leaved group includes several of the most valuable trees of America; among them is *P. rigida*, the pitch pine of the northern states, a tree of from 40 to 50 ft. in height with rugged trunk, occasionally 3 ft. in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. The wood is very hard and abounds with resin, but on swampy land is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the grain is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes.

P. palustris (or *P. australis*) is the "Georgia pitch pine," or yellow pine of the southern states; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on those dry lands attains its highest perfection, though occasionally abundant on moist ground, whence its name. The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk furnishes the most valued pine timber of the states; close-grained and resinous, it is very durable and polishes well; it is largely employed in American shipyards, and immense quantities are exported, especially to Britain and the West Indies. This tree yields an abundant supply of tar and turpentine of good quality, which products are collected and manufactured in the "pine-barrens" on a large scale.

P. Taeda, the "loblolly pine" of the backwoodsman, a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern states, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 or 90 ft. high, having sometimes a girth of 6 or 8 ft., with a broad spreading head; the leaves are rather long and of a light green tint, the cones generally in pairs, the scales terminating in a sharp incurved prickle. The timber of this pine is indifferent, but the forests of it are of importance from the quantity of turpentine they yield; the trees also furnish much firewood of good quality.

P. ponderosa, the yellow pine of the Pacific coast of America, belongs to this section; it is a fine timber tree deserving of notice from the extreme density of its wood, which barely floats in water; it abounds in some parts of the western range of the Rocky Mountains, and is the most widely distributed pine tree of the mountain forests of western North America. The leaves are very long and twisted, the small oval cones armed with recurved prickles; the tree is said to be of rapid growth. In Oregon and California several large pines of this group are found. *P. Coulteri* or *macrocarpa*, is remarkable for its enormous cones (sometimes a foot long, 6 in. in diameter, and weighing more than 4 ℔); the scales end in long hooked points curving upwards; the leaves are long, rigid, and glaucous in hue. Nearly related to this is *P. Sabiniana*, the nut-pine of California, the cones of which are 7 to 9 in. long and 5 to 6 in. in diameter, also with hooked scales; the large nut-like seeds are eaten by the Indians; the tree is one of the largest of the section, sometimes attaining a height of 120 ft. and upwards, while trunks have been found, it is said, 10 or 12 ft. in diameter. *P. longifolia*, a Himalayan species, is remarkable for the great length of its lax slender leaves, of a grass-green tint; the cones have the points of the scales recurved. It is known in India as the "cheer pine"; the wood is good, resinous, and moderately durable; the tree is common on the foot-hills of the Himalayas. *P. Gerardiana*, a north-west Himalayan species, is a medium-sized tree with a conical head, growing on the more elevated parts of the mountain range; it furnishes edible seeds. The leaves, short and glaucous, like those of the Scotch fir, have deciduous sheaths; the cones have recurved scale-points like those of the cheer pine. *P. canariensis*, which forms forests on the mountains of Grand Canary and Teneriffe, growing at an elevation of 6000 ft., also belongs to this group. The leaves are long, lax, and of a bright green tint; the cone-scales are without spines; the trunk attains a large size, and yields good and durable timber. The beautiful Monterey pine, *P. insignis*, distinguished by the brilliant colour of its foliage, has the leaves in tufts of three of four; the lower cone-scales have recurved points. This fine pine has been planted in the south-west of England, but is scarcely hardy.

The pines with five leaves in each tuft have generally deciduous sheaths. The most important economic species is the well-known white pine, *P. Strobus*, from its large growth and abundance, as well as the soft even grain of its white wood, one of the most valuable of North American timber trees. The tree abounds from Canada to Georgia, but in the eastern states has been so long sought for by the lumberer that most of the old trees have long disappeared, and large white pine timber is now only found in quantity in the Canadian Dominion. Formerly Maine and Vermont were celebrated for the size of their pines, but few of these great trees now exist in New England. On a deep rich soil *P. Strobus* attains a height of 150 ft., and trunks without a branch are sometimes found 80 or 90 ft. long; in the earlier stages of growth it has a pyramidal form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The light bluish-green foliage is somewhat lax, very dense in young trees; the cones are long and rather curved, with thin smooth scales a little thickened at the apex, and generally more or less covered with exuding white resin; they are about 5 or 6 in. in length and 1½ to 2 in. broad; the male catkins are of a bluish tint; the cones ripen in the autumn of the second year. The wood of the white pine is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities are still exported, especially from Canada, its smooth easily-worked grain rendering it a favourite wood for the house-carpenter and joiner; it weighs about 28 ℔ per cubic foot. In England where it is generally known as the "Weymouth pine," it succeeds well on deep light soils when well drained; trees have attained occasionally a height of 100 ft. and upwards in British plantations; but it is apt to be infested with American blight (*Eriosoma*). In northern Germany it also grows well. The climate of Scotland

flourishes, and the timber is always indifferent; it is usually said that the wood is best in the cold climate of its more northern habitats, but a trunk (4 ft. in diameter) grown on the sands of Surrey had heart-wood quite equal to any produced in Glenmore or Rothiemurchus. The rapidity of growth is still more variable: in Britain full maturity is attained in from seventy to one hundred and twenty years, but in Norway the trunk increases much more slowly; Schübeler states that a tree felled in the Alten district (about 70° lat.), measuring 2 ft. 10 in. in diameter without the bark, showed four hundred circles of annual growth. In Norway the tree, growing in dense forests, is generally of but moderate girth, and probably this pine nowhere reaches a greater size than in the Scottish woods; a plank from Glenmore forest measured nearly 5½ ft. across, and from 3 to 4½ ft. is not an unusual diameter for a British pine tree.

Vast numbers of Scotch firs are raised in nurseries for artificial planting; the seed is sown in the spring, being just covered with earth, and the seedlings transplanted in the second year into rows for further culture, or taken direct from the seed-bed for final planting; sometimes the seed is sown where the trees are intended to grow. A plantation of Scotch fir requires frequent and careful thinning as the young trees increase in size; but pruning should be avoided as much as possible, excepting for the removal of dead wood. Plantations in England are generally ready for final cutting in from sixty to seventy years, and many are cleared at a much earlier stage of growth. *P. sylvestris* in Britain is liable to many insect depredations: the pine-chafer, *Hylurgus piniperda*, is destructive in some places, the larva of this beetle feeding on the young succulent shoots, especially in young plantations; *Hylobius abietis*, the fir-weevil, eats away the bark, and numerous lepidopterous larvae devour the leaves; the pine-sawfly is also injurious in some seasons; the removal of all dead branches from the trees and from the ground beneath them is recommended, as most of these insects lay their eggs among the decaying bark and dead leaves. In common with other pines, *P. sylvestris* is subject to the attacks of various fungi. *Trametes radiciperda* attacks the roots and penetrates to the stem, causing rotting of the wood; the disease is difficult to eradicate, as the mycelium of the fungus travels from root to root in the soil. Rotting of the wood at the base of the trunk is also caused by *Agaricus melleus*, which spreads from root to root in the soil by means of its long purple-black, cord-like mycelial strands known as *Rhizomorpha*. Much damage is often caused by species of *Peridermium*, which often invade the cortex and cambium to such an extent as to "ring" the stem or branch, or to cause an abnormal formation of turpentine which soaks into the wood and stops the upward passage of water; this causes the parts above the diseased area to perish. In England the pine is largely employed as a "nurse" for oak trees, its conical growth when young admirably adapting it for this purpose; its dense foliage renders it valuable as a shelter tree for protecting land from the wind; it stands the sea gales better than most conifers, but will not flourish on the shore like some other species.

The pine is an important tree in the economy of the northern nations of Europe. In Scandinavia and Russia houses are chiefly constructed of its timber; and log-huts are made of the smaller trunks and lined and roofed with the bark. The inner bark is twisted into ropes, and, like that of the spruce, is kiln dried, ground up, and mixed with meal in times of scarcity; in Kamchatka it is macerated in water, then pounded, and made into a kind of substitute for bread without any admixture of flour. In recent days the fibre of the leaves has been extracted in some quantity and applied to textile purposes under the name of *waldwolle*, both in Germany and Sweden. It is prepared by boiling the needles in a solution of soda to remove the resin, which process loosens the fibre and renders its separation easy; it has some resemblance to coarse wool, and is spun and woven into blankets and garments that are said to be warm and durable; it is also used for stuffing cushions; an essential oil, obtained by a previous distillation of the leaves, has medicinal virtues attributed to it by some German practitioners.

Large quantities of turpentine are extracted from this pine in Sweden and Russia by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is scooped as it accumulates; but the product is not equal to that of the silver fir and other species. Tar is prepared largely from *P. sylvestris*; it is chiefly obtained from the roots, which, mingled with a few logs, are arranged in a conical or funnel-shaped hollow made on the steep side of a hill or bank; after filling up, the whole is covered with turf and fired at the top, when the tar exudes slowly and runs into an iron vessel placed below, from the spout of which it is conveyed into barrels. Most of the so-called Stockholm tar is thus prepared, chiefly in the province of Bothnia.

Closely allied to the Scotch pine, and perhaps to be regarded as a mere alpine form of that species, is the dwarf *P. montana* (or *P. Pumilio*), the "krummholz" or "knieholz" of the Germans—a recumbent bush, generally only a few feet high, but with long zigzag stems, that root occasionally at the knee-like bends where they rest upon the ground. The foliage much resembles that of the Scotch fir, but is shorter, denser and more rigid; the cones are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tirolese Alps, it is a favourite shelter for the chamois; the hunters call it the "latschen," from its recumbent straggling habit. Krummholz oil, valued in Germany as an outward application in rheumatism and for bruises and sprains, is distilled from the young branches, and a fragrant white resin that exudes in some quantity from the buds is used for similar purposes and as a perfume, under the name of Hungarian balsam it is sold in the towns of Germany, being probably obtained from the Carpathians.

The red pine of Canada and New England (so called from the colour of its bark), *P. resinosa*, is a tree of considerable size, sometimes attaining the dimensions of *P. sylvestris*. The somewhat glaucous leaves form dense tufts at the ends of the branches, and are 4 or 5 in. long; the ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch fir, though much employed in ship-building; according to Emerson, trunks exist in Maine 4 ft. in diameter. A sandy soil seems to suit it best, and the quality of the wood probably much depends on its place of growth. Red pines abound in Nova Scotia and Newfoundland, and the tree is rather widely distributed over the northern parts of the continent; it rarely forms extensive woods, but grows chiefly in clumps among other trees, at least in its more southern habitats. Nearly allied is *P. Banksiana*, the grey or Labrador pine, sometimes called the scrub pine from its dwarfish habit; it is the most northerly representative of the genus in America, and is chiefly remarkable for its much recurved and twisted cones, about 2 in. long. The trunks are too small to be of great economic value, but the light wood is used by the natives for their canoes.

P. Laricio, the Corsican pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 ft., with a straight trunk and branches in regular whorls, forming in large trees a pyramidal head; the slender leaves, of a dark green tint, are from 4 to 7 in. long; the cones, either in pairs or several together, project horizontally, and are of a light brown colour. This pine abounds in Corsica, and is found in more or less abundance in Spain, southern France, Greece, and many Mediterranean countries; it occurs on the higher mountains of Cyprus. The tree is of very rapid growth, but produces good timber, much used in southern dockyards, and very durable, though less strong than that of *P. sylvestris*; the heart-wood is of a brownish-tint. In southern France it has been planted with success on the drift-sands of the Bay of Biscay, though it does not bear the full force of the sea-blast as well as the pinaster. In England it grows well in sheltered situations and well-drained soils.

The black pine, *P. austriaca*, generally now regarded as a variety of *P. Laricio*, derives its name from the extreme depth of its foliage tints—the sharp, rigid, rather long leaves of a dark green hue giving a sombre aspect to the tree. The light-coloured, glossy, horizontal cones are generally in pairs, but sometimes three or four together. The tree is conical when young, but when old forms a spreading head; it often attains a large size. Southern Austria and the adjacent countries are the natural habitats of this pine; it seems to flourish best on rocky mountain sides, but in England grows well on sandy soils. The timber is valued in its native country, and is said to be durable and to stand exposure to the weather well; various resinous products are extracted from it. *P. pyrenaica* is a handsome species of pyramidal form, attaining a large size on the mountains of northern Spain, whence it extends through the Mediterranean region to Asia Minor, northern Persia and Afghanistan. The leaves are long and of a light bright green; the cones are solitary, oblong, conical and of a yellow tint. The timber is used in Spanish dockyards, but opinions vary as to its quality. In plantations its bright foliage, with the orange cones and young shoots, render it an ornamental tree, hardy in southern Britain. *P. brutia*, the Calabrian pine, is regarded as the same

species. *P. halepensis*, another Mediterranean form, is valued for its timber, which is white with a fine grain, and resinous products.

P. pinaster, the cluster pine or pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft. or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 in. long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea-sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine, which is largely obtained from the trees by a process analogous to that employed in its collection from *P. sylvestris*; the resin is yielded from May to the end of September, the cuts being renewed as the supply fails, until the tree is exhausted; the trunks are then felled and used in the manufacture of charcoal and lamp black; much tar and pitch is also obtained from these pinaster forests. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; the soft coarse wood, though perishable in the natural state, has been used for railway sleepers after saturation with creosote or preservative solutions.

P. Pinea is the stone pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nut-like seeds, which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid. The tree has been naturalized in many warm countries, even in China; in England it seldom attains any large size, as the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations 20 or 30 ft. in height; the wood, though soft and deficient in the resin that gives durability to the timber of some species, is valued by the southern carpenter and cabinetmaker for its lightness, its fineness of grain, and the ease with which it is worked.

P. mitis, the yellow pine of the northern and middle states of America, is rather allied to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of 70 ft. and upwards, though rarely more than 2 ft. in diameter at the root; the lower branches spread horizontally, the upper, converging towards the trunk, give the tree somewhat the aspect of a spruce, hence it is called in some districts the "spruce-pine." The leaves are long, slender, and of a bluish-green hue; the pendant cones are about 1½ in. long, with a slender point to each scale. The yellow pine is one of the most important timber trees of the genus; the heart-wood being very durable is largely employed in ship-building and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to Britain under the name of "New York yellow pine"; the sapwood is perishable.

The three-leaved group includes several of the most valuable trees of America; among them is *P. rigida*, the pitch pine of the northern states, a tree of from 40 to 50 ft. in height with rugged trunk, occasionally 3 ft. in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. The wood is very hard and abounds with resin, but on swampy land is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the grain is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes.

P. palustris (or *P. australis*) is the "Georgia pitch pine," or yellow pine of the southern states; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on those dry lands attains its highest perfection, though occasionally abundant on moist ground, whence its name. The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk furnishes the most valued pine timber of the states; close-grained and resinous, it is very durable and polishes well; it is largely employed in American shipyards, and immense quantities are exported, especially to Britain and the West Indies. This tree yields an abundant supply of tar and turpentine of good quality, which products are collected and manufactured in the "pine-barrens" on a large scale.

P. Taeda, the "loblolly pine" of the backwoodsman, a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern states, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 or 90 ft. high, having sometimes a girth of 6 or 8 ft., with a broad spreading head; the leaves are rather long and of a light green tint, the cones generally in pairs, the scales terminating in a sharp incurved prickle. The timber of this pine is indifferent, but the forests of it are of importance from the quantity of turpentine they yield; the trees also furnish much firewood of good quality.

P. ponderosa, the yellow pine of the Pacific coast of America, belongs to this section; it is a fine timber tree deserving of notice from the extreme density of its wood, which barely floats in water; it abounds in some parts of the western range of the Rocky Mountains, and is the most widely distributed pine tree of the mountain forests of western North America. The leaves are very long and twisted, the small oval cones armed with recurved prickles; the tree is said to be of rapid growth. In Oregon and California several large pines of this group are found. *P. Coulteri* or *macrocarpa*, is remarkable for its enormous cones (sometimes a foot long, 6 in. in diameter, and weighing more than 4 lb); the scales end in long hooked points curving upwards; the leaves are long, rigid, and glaucous in hue. Nearly related to this is *P. Sabiniana*, the nut-pine of California, the cones of which are 7 to 9 in. long and 5 to 6 in. in diameter, also with hooked scales; the large nut-like seeds are eaten by the Indians; the tree is one of the largest of the section, sometimes attaining a height of 120 ft. and upwards, while trunks have been found, it is said, 10 or 12 ft. in diameter. *P. longifolia*, a Himalayan species, is remarkable for the great length of its lax slender leaves, of a grass-green tint; the cones have the points of the scales recurved. It is known in India as the "cheer pine"; the wood is good, resinous, and moderately durable; the tree is common on the foot-hills of the Himalayas. *P. Gerardiana*, a north-west Himalayan species, is a medium-sized tree with a conical head, growing on the more elevated parts of the mountain range; it furnishes edible seeds. The leaves, short and glaucous, like those of the Scotch fir, have deciduous sheaths; the cones have recurved scale-points like those of the cheer pine. *P. canariensis*, which forms forests on the mountains of Grand Canary and Teneriffe, growing at an elevation of 6000 ft., also belongs to this group. The leaves are long, lax, and of a bright green tint; the cone-scales are without spines; the trunk attains a large size, and yields good and durable timber. The beautiful Monterey pine, *P. insignis*, distinguished by the brilliant colour of its foliage, has the leaves in tufts of three or four; the lower cone-scales have recurved points. This fine pine has been planted in the south-west of England, but is scarcely hardy.

The pines with five leaves in each tuft have generally deciduous sheaths. The most important economic species is the well-known white pine, *P. Strobus*, from its large growth and abundance, as well as the soft even grain of its white wood, one of the most valuable of North American timber trees. The tree abounds from Canada to Georgia, but in the eastern states has been so long sought for by the lumberer that most of the old trees have long disappeared, and large white pine timber is now only found in quantity in the Canadian Dominion. Formerly Maine and Vermont were celebrated for the size of their pines, but few of these great trees now exist in New England. On a deep rich soil *P. Strobus* attains a height of 150 ft., and trunks without a branch are sometimes found 80 or 90 ft. long; in the earlier stages of growth it has a pyramidal form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The light bluish-green foliage is somewhat lax, very dense in young trees; the cones are long and rather curved, with thin smooth scales a little thickened at the apex, and generally more or less covered with exuding white resin; they are about 5 or 6 in. in length and 1½ to 2 in. broad; the male catkins are of a bluish tint; the cones ripen in the autumn of the second year. The wood of the white pine is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities are still exported, especially from Canada, its smooth easily-worked grain rendering it a favourite wood for the house-carpenter and joiner; it weighs about 28 lb per cubic foot. In England where it is generally known as the "Weymouth pine," it succeeds well on deep light soils when well drained; trees have attained occasionally a height of 100 ft. and upwards in British plantations; but it is apt to be infested with American blight (*Eriosoma*). In northern Germany it also grows well. The climate of Scotland

flourishes, and the timber is always indifferent; it is usually said that the wood is best in the cold climate of its more northern habitats, but a trunk (4 ft. in diameter) grown on the sands of Surrey had heart-wood quite equal to any produced in Glenmore or Rothiemurchus. The rapidity of growth is still more variable: in Britain full maturity is attained in from seventy to one hundred and twenty years, but in Norway the trunk increases much more slowly; Schübeler states that a tree felled in the Alten district (about 70° lat.), measuring 2 ft. 10 in. in diameter without the bark, showed four hundred circles of annual growth. In Norway the tree, growing in dense forests, is generally of but moderate girth, and probably this pine nowhere reaches a greater size than in the Scottish woods; a plank from Glenmore forest measured nearly 5½ ft. across, and from 3 to 4½ ft. is not an unusual diameter for a British pine tree.

Vast numbers of Scotch firs are raised in nurseries for artificial planting; the seed is sown in the spring, being just covered with earth, and the seedlings transplanted in the second year into rows for further culture, or taken direct from the seed-bed for final planting; sometimes the seed is sown where the trees are intended to grow. A plantation of Scotch fir requires frequent and careful thinning as the young trees increase in size; but pruning should be avoided as much as possible, excepting for the removal of dead wood. Plantations in England are generally ready for final cutting in from sixty to seventy years, and many are cleared at a much earlier stage of growth. *P. sylvestris* in Britain is liable to many insect depredations: the pine-chafer, *Hylurgus piniperda*, is destructive in some places, the larva of this beetle feeding on the young succulent shoots, especially in young plantations; *Hylobius abietis*, the fir-weevil, eats away the bark, and numerous lepidopterous larvae devour the leaves; the pine-sawfly is also injurious in some seasons; the removal of all dead branches from the trees and from the ground beneath them is recommended, as most of these insects lay their eggs among the decaying bark and dead leaves. In common with other pines, *P. sylvestris* is subject to the attacks of various fungi. *Trametes radiciperda* attacks the roots and penetrates to the stem, causing rotting of the wood; the disease is difficult to eradicate, as the mycelium of the fungus travels from root to root in the soil. Rotting of the wood at the base of the trunk is also caused by *Agaricus melleus*, which spreads from root to root in the soil by means of its long purple-black, cord-like mycelial strands known as *Rhizomorpha*. Much damage is often caused by species of *Peridermium*, which often invade the cortex and cambium to such an extent as to "ring" the stem or branch, or to cause an abnormal formation of turpentine which soaks into the wood and stops the upward passage of water; this causes the parts above the diseased area to perish. In England the pine is largely employed as a "nurse" for oak trees, its conical growth when young admirably adapting it for this purpose; its dense foliage renders it valuable as a shelter tree for protecting land from the wind; it stands the sea gales better than most conifers, but will not flourish on the shore like some other species.

The pine is an important tree in the economy of the northern nations of Europe. In Scandinavia and Russia houses are chiefly constructed of its timber; and log-huts are made of the smaller trunks and lined and roofed with the bark. The inner bark is twisted into ropes, and, like that of the spruce, is kiln dried, ground up, and mixed with meal in times of scarcity; in Kamchatka it is macerated in water, then pounded, and made into a kind of substitute for bread without any admixture of flour. In recent days the fibre of the leaves has been extracted in some quantity and applied to textile purposes under the name of *waldwolle*, both in Germany and Sweden. It is prepared by boiling the needles in a solution of soda to remove the resin, which process loosens the fibre and renders its separation easy; it has some resemblance to coarse wool, and is spun and woven into blankets and garments that are said to be warm and durable; it is also used for stuffing cushions; an essential oil, obtained by a previous distillation of the leaves, has medicinal virtues attributed to it by some German practitioners.

Large quantities of turpentine are extracted from this pine in Sweden and Russia by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is scooped as it accumulates; but the product is not equal to that of the silver fir and other species. Tar is prepared largely from *P. sylvestris*; it is chiefly obtained from the roots, which, mingled with a few logs, are arranged in a conical or funnel-shaped hollow made on the steep side of a hill or bank; after filling up, the whole is covered with turf and fired at the top, when the tar exudes slowly and runs into an iron vessel placed below, from the spout of which it is conveyed into barrels. Most of the so-called Stockholm tar is thus prepared, chiefly in the province of Bothnia.

Closely allied to the Scotch pine, and perhaps to be regarded as a mere alpine form of that species, is the dwarf *P. montana* (or *P. Pumilio*), the "krummholz" or "knieholz" of the Germans—a recumbent bush, generally only a few feet high, but with long zigzag stems, that root occasionally at the knee-like bends where they rest upon the ground. The foliage much resembles that of the Scotch fir, but is shorter, denser and more rigid; the cones are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tirolese Alps, it is a favourite shelter for the chamois; the hunters call it the "latschen," from its recumbent straggling habit. Krummholz oil, valued in Germany as an outward application in rheumatism and for bruises and sprains, is distilled from the young branches, and a fragrant white resin that exudes in some quantity from the buds is used for similar purposes and as a perfume, under the name of Hungarian balsam it is sold in the towns of Germany, being probably obtained from the Carpathians.

The red pine of Canada and New England (so called from the colour of its bark), *P. resinosa*, is a tree of considerable size, sometimes attaining the dimensions of *P. sylvestris*. The somewhat glaucous leaves form dense tufts at the ends of the branches, and are 4 or 5 in. long; the ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch fir, though much employed in ship-building; according to Emerson, trunks exist in Maine 4 ft. in diameter. A sandy soil seems to suit it best, and the quality of the wood probably much depends on its place of growth. Red pines abound in Nova Scotia and Newfoundland, and the tree is rather widely distributed over the northern parts of the continent; it rarely forms extensive woods, but grows chiefly in clumps among other trees, at least in its more southern habitats. Nearly allied is *P. Banksiana*, the grey or Labrador pine, sometimes called the scrub pine from its dwarfish habit; it is the most northerly representative of the genus in America, and is chiefly remarkable for its much recurved and twisted cones, about 2 in. long. The trunks are too small to be of great economic value, but the light wood is used by the natives for their canoes.

P. Laricio, the Corsican pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 ft., with a straight trunk and branches in regular whorls, forming in large trees a pyramidal head; the slender leaves, of a dark green tint, are from 4 to 7 in. long; the cones, either in pairs or several together, project horizontally, and are of a light brown colour. This pine abounds in Corsica, and is found in more or less abundance in Spain, southern France, Greece, and many Mediterranean countries; it occurs on the higher mountains of Cyprus. The tree is of very rapid growth, but produces good timber, much used in southern dockyards, and very durable, though less strong than that of *P. sylvestris*; the heart-wood is of a brownish-tint. In southern France it has been planted with success on the drift-sands of the Bay of Biscay, though it does not bear the full force of the sea-blast as well as the pinaster. In England it grows well in sheltered situations and well-drained soils.

The black pine, *P. austriaca*, generally now regarded as a variety of *P. Laricio*, derives its name from the extreme depth of its foliage tints—the sharp, rigid, rather long leaves of a dark green hue giving a sombre aspect to the tree. The light-coloured, glossy, horizontal cones are generally in pairs, but sometimes three or four together. The tree is conical when young, but when old forms a spreading head; it often attains a large size. Southern Austria and the adjacent countries are the natural habitats of this pine; it seems to flourish best on rocky mountain sides, but in England grows well on sandy soils. The timber is valued in its native country, and is said to be durable and to stand exposure to the weather well; various resinous products are extracted from it. *P. pyrenaica* is a handsome species of pyramidal form, attaining a large size on the mountains of northern Spain, whence it extends through the Mediterranean region to Asia Minor, northern Persia and Afghanistan. The leaves are long and of a light bright green; the cones are solitary, oblong, conical and of a yellow tint. The timber is used in Spanish dockyards, but opinions vary as to its quality. In plantations its bright foliage, with the orange cones and young shoots, render it an ornamental tree, hardy in southern Britain. *P. brutia*, the Calabrian pine, is regarded as the same

species. *P. halepensis*, another Mediterranean form, is valued for its timber, which is white with a fine grain, and resinous products.

P. pinaster, the cluster pine or pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft. or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 in. long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea-sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine, which is largely obtained from the trees by a process analogous to that employed in its collection from *P. sylvestris*; the resin is yielded from May to the end of September, the cuts being renewed as the supply fails, until the tree is exhausted; the trunks are then felled and used in the manufacture of charcoal and lamp black; much tar and pitch is also obtained from these pinaster forests. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; the soft coarse wood, though perishable in the natural state, has been used for railway sleepers after saturation with creosote or preservative solutions.

P. Pinea is the stone pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nut-like seeds, which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid. The tree has been naturalized in many warm countries, even in China; in England it seldom attains any large size, as the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations 20 or 30 ft. in height; the wood, though soft and deficient in the resin that gives durability to the timber of some species, is valued by the southern carpenter and cabinetmaker for its lightness, its fineness of grain, and the ease with which it is worked.

P. mitis, the yellow pine of the northern and middle states of America, is rather allied to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of 70 ft. and upwards, though rarely more than 2 ft. in diameter at the root; the lower branches spread horizontally, the upper, converging towards the trunk, give the tree somewhat the aspect of a spruce, hence it is called in some districts the "spruce-pine." The leaves are long, slender, and of a bluish-green hue; the pendant cones are about 1½ in. long, with a slender point to each scale. The yellow pine is one of the most important timber trees of the genus; the heart-wood being very durable is largely employed in ship-building and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to Britain under the name of "New York yellow pine"; the sapwood is perishable.

The three-leaved group includes several of the most valuable trees of America; among them is *P. rigida*, the pitch pine of the northern states, a tree of from 40 to 50 ft. in height with rugged trunk, occasionally 3 ft. in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. The wood is very hard and abounds with resin, but on swampy land is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the grain is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes.

P. palustris (or *P. australis*) is the "Georgia pitch pine," or yellow pine of the southern states; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on those dry lands attains its highest perfection, though occasionally abundant on moist ground, whence its name. The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk furnishes the most valued pine timber of the states; close-grained and resinous, it is very durable and polishes well; it is largely employed in American shipyards, and immense quantities are exported, especially to Britain and the West Indies. This tree yields an abundant supply of tar and turpentine of good quality, which products are collected and manufactured in the "pine-barrens" on a large scale.

P. Taeda, the "loblolly pine" of the backwoodsman, a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern states, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 or 90 ft. high, having sometimes a girth of 6 or 8 ft., with a broad spreading head; the leaves are rather long and of a light green tint, the cones generally in pairs, the scales terminating in a sharp incurved prickle. The timber of this pine is indifferent, but the forests of it are of importance from the quantity of turpentine they yield; the trees also furnish much firewood of good quality.

P. ponderosa, the yellow pine of the Pacific coast of America, belongs to this section; it is a fine timber tree deserving of notice from the extreme density of its wood, which barely floats in water; it abounds in some parts of the western range of the Rocky Mountains, and is the most widely distributed pine tree of the mountain forests of western North America. The leaves are very long and twisted, the small oval cones armed with recurved prickles; the tree is said to be of rapid growth. In Oregon and California several large pines of this group are found. *P. Coulteri* or *macrocarpa*, is remarkable for its enormous cones (sometimes a foot long, 6 in. in diameter, and weighing more than 4 ℔); the scales end in long hooked points curving upwards; the leaves are long, rigid, and glaucous in hue. Nearly related to this is *P. Sabiniana*, the nut-pine of California, the cones of which are 7 to 9 in. long and 5 to 6 in. in diameter, also with hooked scales; the large nut-like seeds are eaten by the Indians; the tree is one of the largest of the section, sometimes attaining a height of 120 ft. and upwards, while trunks have been found, it is said, 10 or 12 ft. in diameter. *P. longifolia*, a Himalayan species, is remarkable for the great length of its lax slender leaves, of a grass-green tint; the cones have the points of the scales recurved. It is known in India as the "cheer pine"; the wood is good, resinous, and moderately durable; the tree is common on the foot-hills of the Himalayas. *P. Gerardiana*, a north-west Himalayan species, is a medium-sized tree with a conical head, growing on the more elevated parts of the mountain range; it furnishes edible seeds. The leaves, short and glaucous, like those of the Scotch fir, have deciduous sheaths; the cones have recurved scale-points like those of the cheer pine. *P. canariensis*, which forms forests on the mountains of Grand Canary and Teneriffe, growing at an elevation of 6000 ft., also belongs to this group. The leaves are long, lax, and of a bright green tint; the cone-scales are without spines; the trunk attains a large size, and yields good and durable timber. The beautiful Monterey pine, *P. insignis*, distinguished by the brilliant colour of its foliage, has the leaves in tufts of three of four; the lower cone-scales have recurved points. This fine pine has been planted in the south-west of England, but is scarcely hardy.

The pines with five leaves in each tuft have generally deciduous sheaths. The most important economic species is the well-known white pine, *P. Strobus*, from its large growth and abundance, as well as the soft even grain of its white wood, one of the most valuable of North American timber trees. The tree abounds from Canada to Georgia, but in the eastern states has been so long sought for by the lumberer that most of the old trees have long disappeared, and large white pine timber is now only found in quantity in the Canadian Dominion. Formerly Maine and Vermont were celebrated for the size of their pines, but few of these great trees now exist in New England. On a deep rich soil *P. Strobus* attains a height of 150 ft., and trunks without a branch are sometimes found 80 or 90 ft. long; in the earlier stages of growth it has a pyramidal form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The light bluish-green foliage is somewhat lax, very dense in young trees; the cones are long and rather curved, with thin smooth scales a little thickened at the apex, and generally more or less covered with exuding white resin; they are about 5 or 6 in. in length and 1½ to 2 in. broad; the male catkins are of a bluish tint; the cones ripen in the autumn of the second year. The wood of the white pine is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities are still exported, especially from Canada, its smooth easily-worked grain rendering it a favourite wood for the house-carpenter and joiner; it weighs about 28 ℔ per cubic foot. In England where it is generally known as the "Weymouth pine," it succeeds well on deep light soils when well drained; trees have attained occasionally a height of 100 ft. and upwards in British plantations; but it is apt to be infested with American blight (*Eriosoma*). In northern Germany it also grows well. The climate of Scotland

In three-handed pinochle the "melds" are exposed before a card is played, and no player may "meld" after he has played to the first trick. A rule is sometimes made that an overlooked combination may be scored by the other players. Four-handed pinochle is played either with partners or each player for himself.

PINSK, a town of Russia, in the government of Minsk, at the confluence of the Strumen and Pina rivers, 196 m. S.W. by rail of Minsk. Pop. 27,938, two-thirds being Jews. The town carries on considerable trade, due to the navigable river Pina, which connects it with the fertile regions in the basin of the Dnieper, and, by means of the Dnieper-and-Bug canal, with Poland and Prussia, while the Oginsky canal connects it with the basin of the Niemen. Pottery, leather, oil, soap and beer are the chief products of the local industries. The draining of the marshes around Pinsk was begun by the government in 1872, and by 1897 8 million acres had been drained at an average cost of 3s. per acre. Pinsk (Pinesk) is first mentioned in 1097 as a town belonging to Sviatopolk, prince of Kiev. In 1132 it formed part of the Minsk principality. After the Mongol invasion of 1239–42 it became the chief town of a separate principality, and continued to be so until the end of the 13th century. In 1320 it was annexed to Lithuania; and in 1569, after the union of Lithuania with Poland, it was chief town of the province of Brest. During the rebellion of the Cossack chief, Bogdan Chmielnicki (1640), the Poles took it by assault, killing 14,000 persons and burning 5000 houses. Eight years later the town was burned by the Russians. Charles XII. took it in 1706, and burned the town with its suburbs. Pinsk was annexed to Russia in 1795.

PINSUTI, CIRO (1829–1888), Anglo-Italian composer, was born at Siena, and was educated in music, for a career as a pianist, partly in London and partly at Bologna, where he was a pupil of Rossini. From 1848 he made his home in England, where he became a teacher of singing, and in 1856 he was made a professor at the Academy of Music in London. He became well known as a composer of numerous favourite songs and part-songs, as well as of three operas brought out in Italy, and it is by the former that he is still remembered.

PINT (derived probably through Spanish, from Lat. *pincta, picta*, a painted or marked vessel), a liquid measure of capacity, equivalent to ⅛ of a gallon. The imperial British pint = ·57 of a litre, 34·66 cub. in. The United States standard pint = ·47 of a litre, 28⅞ cub. in. The word appears in French as *pinte* for a liquid measure as early as the 13th century.

PINTO, ANÍBAL (1825–1884), Chilean president, was born at Santiago, Chile. After a diplomatic training in the legation at Rome he learned the practice of administration as *intendente* of Concepcion, and from 1871 to 1876 was minister of war and marine under Errázuriz. During his term of office as president (1876 to 1881) Pinto had to deal first with a severe financial crisis, and then to conduct the struggle with Peru and Bolivia, in which he displayed great coolness of judgment and devotion to duty.

PINTO, FERNÃO MENDES (1509–1583), Portuguese adventurer, was born at Montemôr-o-Velho, of poor and humble parents, and entered the service of a noble lady in Lisbon, being afterwards for two years page to the duke of Aveiro in Setubal. Desiring to try his fortune in the East, he embarked for India in 1537 in a fleet commanded by the son of Vasco da Gama, and for twenty-one years travelled, fought and traded in China, Tartary, Pegu and the neighbouring countries, sailing in every sea, while in 1542–1543 he was one of the first Europeans to visit Japan, where he introduced the musket. Though he was thirteen times a captive and seventeen times sold into slavery, his gay and dauntless spirit brought him through every misfortune. He was soldier and sailor, merchant and doctor, missionary and ambassador; moreover, as the friend and travelling companion of St Francis Xavier, he lent the apostle of the Indies the money with which to build the first Jesuit establishment in Japan. In January 1554 Mendes Pinto was in Goa, waiting for a ship to take him to Portugal, when he took a sudden resolution to enter the company of Jesus and devote a large part of the capital he had accumulated to the evangelization of Japan. The viceroy appointed him ambassador to the king of Bungo in order to give the mission an official standing, and on the 18th of April he set sail with the provincial, Father Belchior Nunes. Owing to bad weather and contrary winds, however, the missioners did not reach Japan until July 1556, but the success of the mission represented a notable service to the cause of Christianity and civilization. On the 14th of November 1556 Father Belchior and Mendes Pinto began their return voyage and reached Goa on the 17th of February 1557. During his stay of a twelvemonth there, the latter left the company, being dispensed from his vows for want of vocation at his own request, though a modern authority states that he was expelled because he was found to be a *marrano, i.e.* to possess Jewish blood. He finally returned to Portugal on the 22nd of September 1558, and settled at Pragal near Almada, where he married and wrote his famous book, the *Peregrination*; the MS., in fulfilment of his wishes, was presented by his daughter to the Casa Pia for penitent women in Lisbon, and it was published by the administrators in 1614. When Philip II. of Spain came to Portugal as its king, he listened with pleasure to the account of Mendes Pinto's travels, and by letter of the 15th of January 1583 gave him a pension for his services in the Indies. But the reward came too late, for the great traveller died on the 8th of July.

In the light of our present-day knowledge of the East, Pinto is regarded as having been on the whole a careful observer and truthful narrator, but this was not always the case. Some witty countryman of his own parodied his name into *Fernão, mentes? Minto!* ("Ferdinand, do you lie? I do!"); and the English dramatist Congreve only expressed the general opinion of the unlearned when he wrote, in *Love for Love*, "Mendez Pinto was but a type of thee, thou liar of the first magnitude." It must be remembered that Pinto wrote the *Peregrination* long subsequent to the events he records, and this fact and a certain fertility of imagination sufficiently account for inexactitudes. Furthermore, as the book was only published posthumously, he never had the opportunity of correcting the proofs. Some of his most marvellous stories are expressly given on the authority of writers belonging to the countries he describes; others he tells from hearsay, and Oriental informants are prone to exaggeration. But if he somewhat adorned the truth, he did not wilfully misrepresent it. The book itself gives the impression of sincerity, and the editors of the first edition bear witness to the probity, good faith and truthfulness of Mendes Pinto as a man. Herrera Maldonado prefaced his Spanish translation of the *Peregrination* (1620) by a lengthy and erudite apology to demonstrate its authenticity, and Castilho has reinforced his arguments by modern testimonies. In the narrative portions of his work Pinto's style is simple, clear and natural, his diction rich, particularly in sea terms, and appropriate to his varying subjects. There is an entire absence of artifice about the book, which must always rank as a classic, and it might fairly be argued that Mendes Pinto did for the prose of Portugal what Camoens did for its poetry; this is the more remarkable, because it does not appear that he ever received any education in the ordinary sense. He wrote the book for his children to learn to read by, and modestly excused its literary defects by alleging his rudeness and lack of talent. Tradition has it that the MS. was entrusted to the chronicler Francisco de Andrade for the purpose of being polished in style and made ready for press, but that all he did was to divide it into chapters.

The *Peregrination* has gone through many editions subsequent to that of 1614, and in 1865 Castilho published excerpts in his *Livraria classica portugueza* with an interesting notice of Mendes Pinto's life and writings. Versions exist in German (3 editions), French (3 editions), Spanish (4 editions), and in English by Henry Cogan, London (1663, 1692 and—abridged and illustrated, with introduction by Arminius Vambéry—1891). Cogan omits the chapters relating to Mendes Pinto's intercourse with, and the last days of, St Francis Xavier, presumably as a concession to anti-Catholic prejudice.

See Christovão Ayres, *Fernão Mendes Pinto* (Lisbon, 1904), *Fernão Mendes Pinto e o Japão* (Lisbon, 1906); also *Subsidios . . . para a biographia de Fernão Mendes Pinto* by Jordão de Freitas (Coimbra, 1905).

(E. Pr.)

species. *P. halepensis*, another Mediterranean form, is valued for its timber, which is white with a fine grain, and resinous products.

P. pinaster, the cluster pine or pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft. or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 in. long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea-sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine, which is largely obtained from the trees by a process analogous to that employed in its collection from *P. sylvestris*; the resin is yielded from May to the end of September, the cuts being renewed as the supply fails, until the tree is exhausted; the trunks are then felled and used in the manufacture of charcoal and lamp black; much tar and pitch is also obtained from these pinaster forests. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; the soft coarse wood, though perishable in the natural state, has been used for railway sleepers after saturation with creosote or preservative solutions.

P. Pinea is the stone pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nut-like seeds, which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid. The tree has been naturalized in many warm countries, even in China; in England it seldom attains any large size, as the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations 20 or 30 ft. in height; the wood, though soft and deficient in the resin that gives durability to the timber of some species, is valued by the southern carpenter and cabinetmaker for its lightness, its fineness of grain, and the ease with which it is worked.

P. mitis, the yellow pine of the northern and middle states of America, is rather allied to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of 70 ft. and upwards, though rarely more than 2 ft. in diameter at the root; the lower branches spread horizontally, the upper, converging towards the trunk, give the tree somewhat the aspect of a spruce, hence it is called in some districts the "spruce-pine." The leaves are long, slender, and of a bluish-green hue; the pendant cones are about 1½ in. long, with a slender point to each scale. The yellow pine is one of the most important timber trees of the genus; the heart-wood being very durable is largely employed in ship-building and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to Britain under the name of "New York yellow pine"; the sapwood is perishable.

The three-leaved group includes several of the most valuable trees of America; among them is *P. rigida*, the pitch pine of the northern states, a tree of from 40 to 50 ft. in height with rugged trunk, occasionally 3 ft. in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. The wood is very hard and abounds with resin, but on swampy land is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the grain is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes.

P. palustris (or *P. australis*) is the "Georgia pitch pine," or yellow pine of the southern states; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on those dry lands attains its highest perfection, though occasionally abundant on moist ground, whence its name. The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk furnishes the most valued pine timber of the states; close-grained and resinous, it is very durable and polishes well; it is largely employed in American shipyards, and immense quantities are exported, especially to Britain and the West Indies. This tree yields an abundant supply of tar and turpentine of good quality, which products are collected and manufactured in the "pine-barrens" on a large scale.

P. Taeda, the "loblolly pine" of the backwoodsman, a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern states, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 or 90 ft. high, having sometimes a girth of 6 or 8 ft., with a broad spreading head; the leaves are rather long and of a light green tint, the cones generally in pairs, the scales terminating in a sharp incurved prickle. The timber of this pine is indifferent, but the forests of it are of importance from the quantity of turpentine they yield; the trees also furnish much firewood of good quality.

P. ponderosa, the yellow pine of the Pacific coast of America, belongs to this section; it is a fine timber tree deserving of notice from the extreme density of its wood, which barely floats in water; it abounds in some parts of the western range of the Rocky Mountains, and is the most widely distributed pine tree of the mountain forests of western North America. The leaves are very long and twisted, the small oval cones armed with recurved prickles; the tree is said to be of rapid growth. In Oregon and California several large pines of this group are found. *P. Coulteri* or *macrocarpa*, is remarkable for its enormous cones (sometimes a foot long, 6 in. in diameter, and weighing more than 4 ℔); the scales end in long hooked points curving upwards; the leaves are long, rigid, and glaucous in hue. Nearly related to this is *P. Sabiniana*, the nut-pine of California, the cones of which are 7 to 9 in. long and 5 to 6 in. in diameter, also with hooked scales; the large nut-like seeds are eaten by the Indians; the tree is one of the largest of the section, sometimes attaining a height of 120 ft. and upwards, while trunks have been found, it is said, 10 or 12 ft. in diameter. *P. longifolia*, a Himalayan species, is remarkable for the great length of its lax slender leaves, of a grass-green tint; the cones have the points of the scales recurved. It is known in India as the "cheer pine"; the wood is good, resinous, and moderately durable; the tree is common on the foot-hills of the Himalayas. *P. Gerardiana*, a north-west Himalayan species, is a medium-sized tree with a conical head, growing on the more elevated parts of the mountain range; it furnishes edible seeds. The leaves, short and glaucous, like those of the Scotch fir, have deciduous sheaths; the cones have recurved scale-points like those of the cheer pine. *P. canariensis*, which forms forests on the mountains of Grand Canary and Teneriffe, growing at an elevation of 6000 ft., also belongs to this group. The leaves are long, lax, and of a bright green tint; the cone-scales are without spines; the trunk attains a large size, and yields good and durable timber. The beautiful Monterey pine, *P. insignis*, distinguished by the brilliant colour of its foliage, has the leaves in tufts of three of four; the lower cone-scales have recurved points. This fine pine has been planted in the south-west of England, but is scarcely hardy.

The pines with five leaves in each tuft have generally deciduous sheaths. The most important economic species is the well-known white pine, *P. Strobus*, from its large growth and abundance, as well as the soft even grain of its white wood, one of the most valuable of North American timber trees. The tree abounds from Canada to Georgia, but in the eastern states has been so long sought for by the lumberer that most of the old trees have long disappeared, and large white pine timber is now only found in quantity in the Canadian Dominion. Formerly Maine and Vermont were celebrated for the size of their pines, but few of these great trees now exist in New England. On a deep rich soil *P. Strobus* attains a height of 150 ft., and trunks without a branch are sometimes found 80 or 90 ft. long; in the earlier stages of growth it has a pyramidal form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The light bluish-green foliage is somewhat lax, very dense in young trees; the cones are long and rather curved, with thin smooth scales a little thickened at the apex, and generally more or less covered with exuding white resin; they are about 5 or 6 in. in length and 1½ to 2 in. broad; the male catkins are of a bluish tint; the cones ripen in the autumn of the second year. The wood of the white pine is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities are still exported, especially from Canada, its smooth easily-worked grain rendering it a favourite wood for the house-carpenter and joiner; it weighs about 28 ℔ per cubic foot. In England where it is generally known as the "Weymouth pine," it succeeds well on deep light soils when well drained; trees have attained occasionally a height of 100 ft. and upwards in British plantations; but it is apt to be infested with American blight (*Eriosoma*). In northern Germany it also grows well. The climate of Scotland

in the cathedral of Spello, in the Siena gallery, at Florence, at Perugia, and in other collections.

In 1501 Pinturicchio painted several fine frescoes in S. Maria Maggiore at Spello—all very decorative and full of elaborate architectural accessories. One of them, the Annunciation, is signed "Bernardinvs Pintvrichivs Pervsinvs." The most striking of all Pinturicchio's frescoes, both for brilliance of colour and their wonderful state of preservation, are those in the cathedral library at Siena, a large room built in 1495 by Cardinal Francesco Piccolomini, afterwards Pius III. In 1502 the cardinal contracted with Pinturicchio to decorate the whole room with arabesques on the vault, and on the walls ten scenes from the life of Aeneas Sylvius Piccolomini, Pius II., the uncle of Cardinal Francesco.

The contract specially provided that the cartoons, their transference on to the walls, and all the heads, were to be by Pinturicchio's own hand, thus contradicting Vasari's assertion that the cartoons were the work of Raphael. The document provides for the price of these frescoes, namely one thousand gold ducats, to be paid in various instalments. The work was begun early in 1503, but was interrupted for a while by the death of Pius III. His will, however, provided for the completion of the work by his executors, and the whole series were finished in 1507. The subjects are (1) the journey of the young Sylvius Piccolomini to the Council of Basel, in the suite of Cardinal Capranica; (2) his reception by James I. of Scotland as envoy from the Council of Basel; (3) his being crowned with the poet's laurel by Frederick III.; (4) his reception by Pope Eugenius IV. as ambassador from Frederick III.; (5) outside the wall of Siena he presents to Frederick III. his bride Leonora, infanta of Portugal; (6) he receives the cardinal's hat from Pope Calixtus III.; (7) he is borne in procession after his election as Pope Pius II.; (8) he presides at a council at Mantua; (9) he canonizes St Catherine of Siena; (10) he arrives in Ancona to promote the crusade against the Turks. In addition to these there is, outside the library, over the door, the coronation of Pius III. In the lower part of the scene of St Catherine's canonization he has introduced his own portrait, and standing by him is a youth who bears some resemblance to Raphael.

In 1508 Pinturicchio painted another panel of the Madonna enthroned among saints for the church of the Minori Conventuali at Spello. It is now over the altar in the sacristy. On his return to Siena he painted a whole series of frescoes on the walls of the Palazzo Petrucci, now all destroyed except one scene of the return of Ulysses to Penelope (or possibly Collatinus and Lucretia), which is now in the National Gallery of London, transferred to canvas. One of his last works, painted in 1513, the year of his death, is a very beautiful and highly finished panel with Christ bearing His Cross, now in the Palazzo Borromeo in Milan. Pinturicchio married Grania di Niccolò, and had by her two sons and four daughters; there is probably no truth in the story of his being starved by his wife during his last illness.

Pinturicchio's worth as a painter has been for the most part undervalued, partly owing to the very strong prejudice and dislike which tinges Vasari's biography of him. Even Crowe and Cavalcaselle hardly did him justice. A fairer estimate of his position in the history of art is given by Vermiglioli, *Memorie di Pinturicchio* (Perugia, 1837); and in the valuable notes and appendix of Milanesi's edition of Vasari, iii. 493–531 (Florence, 1878). See also Schmarsow, *Raphael und Pinturicchio in Siena* (Stuttgart, 1880), and *Pinturicchio in Rom* (Stuttgart, 1882), both well illustrated by photo-lithography. (J. H. M.)

PINWELL, GEORGE JOHN (1842–1875), British water-colour painter, was born at Wycombe, and educated at Heatherley's Academy. He is one of the most interesting personalities in the little group of water-colour painters which included Frederick Walker and A. B. Houghton, a group whose style was directly derived from the practice of drawing upon wood for book illustration. He was one of the most delightful book illustrators of his day, poetic in imagination, with considerable inventive power and an admirable sense of colour. As he died young his works are few, but their promise was so great that had he lived he would probably have attained a very high position. His early life was one of considerable privation. In 1862 he entered at Heatherley's studio and there obtained his art education. His earliest drawings appeared in *Lilliput Levée*. He did a little work for *Fun* and executed several designs for the silversmiths, Elkingtons. In 1863 his first drawing appeared in *Once a Week*, and from that time his work was in constant demand. There are many of his compositions in *Good Words*, *The Sunday Magazine*, *The Quiver* and *London Society*, but his most important productions made for the Dalziel brothers were illustrations of Goldsmith, of Jean Ingelow's poems, Robert Buchanan's *Ballads of the Affections*, and the *Arabian Nights*.

Of Pinwell's pictures in colour, which are distinguished by a remarkable, jewel-like quality and marked by his strong love of pure, bright colour and opalescent effect, the chief are the two scenes from the *Pied Piper of Hamelin*, *Gilbert à Becket's Troth*, *Out of Tune* or *The Old Cross*, *A Seat in St James's Park*, and *The Elixir of Life*.

In 1874 Pinwell fell seriously ill and went to Africa for the winter. He painted several remarkable pictures at Tangier, but his strength gradually broke down and he returned to die in his wife's arms on the 8th of September 1875. Pinwell was an exhibitor at the Dudley gallery, and in 1869 was elected associate of the Royal Water-Colour Society and full member in 1870; to this gallery he contributed fifty-nine works. A posthumous exhibition of his works was held in 1876 in Bond Street.

See *Life of George J. Pinwell*, by George C. Williamson, quarto, 1900. (G. C. W.)

PINZON, a family of wealthy Spanish navigators, of Palos in Andalusia, three members of which—Martin Alonzo, Francisco and Vicente Yañez, brothers—were associated with Columbus in the discovery of America.

Martin Alonzo Pinzon, born about the middle of the 15th century, gave material assistance to Columbus in carrying out his project. "If Colon was the head, Pinzon was the right arm" (Asensio). In the expedition of 1492 he commanded the "Pinta," on which his brother Francisco was pilot; another brother, Vicente Yañez, commanded the "Nina." On the 6th of October Martin Alonzo suggested to Columbus (when already in the longitude of the Bermudas) to change the course of the expedition from due west to south-west; on the 7th of October this suggestion—strengthened by the observation of a flight of birds to the south-west—was adopted, bringing the fleet, four days later, to the landfall at Guanahani (San Salvador, Watling Island) in the Bahamas (Oct. 12, 1492). On the 21st of November 1492, near the east end of the north coast of Cuba, Martin Alonzo left Columbus, making eastward in search of the gold-land of which they had heard the natives speak. On the 6th of January 1493 he rejoined the admiral, who accepted his excuses. But on the return journey he again left his leader, and when Columbus arrived at Palos on the 15th of March 1493 he learned that Alonzo had already landed at Bayona in Galicia. If his object was to forestall Columbus and pose as discoverer of the New World, he was foiled; audience was refused him by Ferdinand and Isabella; and soon after he died, perhaps of chagrin.

Vicente Yañez Pinzon, who commanded the "Nina" in 1492–1493, also gave Columbus material help, and remained loyal to his leader throughout. In after years he made important discoveries on his own account. Late in December 1499 he sailed with four caravels across the Atlantic to the south-west, and on the 7th of February 1500 he struck the South American continent at Cape S. Agostinho, near its most easterly projection (called by him Cape Santa Maria de la Consolacion), almost three months before the Portuguese navigator Cabral reached Brazil, the discovery of which is generally attributed to him. Proceeding southwards a short distance, he then turned north, followed the coast to the north-west, discovered the Amazon estuary, and went at least as far as what is now Costa Rica. After touching at Haiti, and losing two of his vessels among the Bahamas, Vicente returned to Palos in the end of September 1500. Although concessions were made to him, and he was created governor of the newly discovered lands by Ferdinand and Isabella, he does not seem to have ever taken possession. In 1507 we find Vicente sailing with Juan Diaz de Solis along the east coast of Central America. In 1509, again with De Solis, he coasted the Atlantic side of South America as far as the La Plata estuary, hoping to find an opening westwards leading to the Spice Islands. According to Herrera, he even reached 40° S.,

species. *P. halepensis*, another Mediterranean form, is valued for its timber, which is white with a fine grain, and resinous products.

P. pinaster, the cluster pine or pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft. or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 in. long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea-sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine, which is largely obtained from the trees by a process analogous to that employed in its collection from *P. sylvestris*; the resin is yielded from May to the end of September, the cuts being renewed as the supply fails, until the tree is exhausted; the trunks are then felled and used in the manufacture of charcoal and lamp black; much tar and pitch is also obtained from these pinaster forests. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; the soft coarse wood, though perishable in the natural state, has been used for railway sleepers after saturation with creosote or preservative solutions.

P. Pinea is the stone pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nut-like seeds, which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid. The tree has been naturalized in many warm countries, even in China; in England it seldom attains any large size, as the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations 20 or 30 ft. in height; the wood, though soft and deficient in the resin that gives durability to the timber of some species, is valued by the southern carpenter and cabinetmaker for its lightness, its fineness of grain, and the ease with which it is worked.

P. mitis, the yellow pine of the northern and middle states of America, is rather allied to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of 70 ft. and upwards, though rarely more than 2 ft. in diameter at the root; the lower branches spread horizontally, the upper, converging towards the trunk, give the tree somewhat the aspect of a spruce, hence it is called in some districts the "spruce-pine." The leaves are long, slender, and of a bluish-green hue; the pendant cones are about 1½ in. long, with a slender point to each scale. The yellow pine is one of the most important timber trees of the genus; the heart-wood being very durable is largely employed in ship-building and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to Britain under the name of "New York yellow pine"; the sapwood is perishable.

The three-leaved group includes several of the most valuable trees of America; among them is *P. rigida*, the pitch pine of the northern states, a tree of from 40 to 50 ft. in height with rugged trunk, occasionally 3 ft. in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. The wood is very hard and abounds with resin, but on swampy land is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the grain is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes.

P. palustris (or *P. australis*) is the "Georgia pitch pine," or yellow pine of the southern states; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on those dry lands attains its highest perfection, though occasionally abundant on moist ground, whence its name. The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk furnishes the most valued pine timber of the states; close-grained and resinous, it is very durable and polishes well; it is largely employed in American shipyards, and immense quantities are exported, especially to Britain and the West Indies. This tree yields an abundant supply of tar and turpentine of good quality, which products are collected and manufactured in the "pine-barrens" on a large scale.

P. Taeda, the "loblolly pine" of the backwoodsman, a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern states, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 or 90 ft. high, having sometimes a girth of 6 or 8 ft., with a broad spreading head; the leaves are rather long and of a light green tint, the cones generally in pairs, the scales terminating in a sharp incurved prickle. The timber of this pine is indifferent, but the forests of it are of importance from the quantity of turpentine they yield; the trees also furnish much firewood of good quality.

P. ponderosa, the yellow pine of the Pacific coast of America, belongs to this section; it is a fine timber tree deserving of notice from the extreme density of its wood, which barely floats in water; it abounds in some parts of the western range of the Rocky Mountains, and is the most widely distributed pine tree of the mountain forests of western North America. The leaves are very long and twisted, the small oval cones armed with recurved prickles; the tree is said to be of rapid growth. In Oregon and California several large pines of this group are found. *P. Coulteri* or *macrocarpa*, is remarkable for its enormous cones (sometimes a foot long, 6 in. in diameter, and weighing more than 4 ℔); the scales end in long hooked points curving upwards; the leaves are long, rigid, and glaucous in hue. Nearly related to this is *P. Sabiniana*, the nut-pine of California, the cones of which are 7 to 9 in. long and 5 to 6 in. in diameter, also with hooked scales; the large nut-like seeds are eaten by the Indians; the tree is one of the largest of the section, sometimes attaining a height of 120 ft. and upwards, while trunks have been found, it is said, 10 or 12 ft. in diameter. *P. longifolia*, a Himalayan species, is remarkable for the great length of its lax slender leaves, of a grass-green tint; the cones have the points of the scales recurved. It is known in India as the "cheer pine"; the wood is good, resinous, and moderately durable; the tree is common on the foot-hills of the Himalayas. *P. Gerardiana*, a north-west Himalayan species, is a medium-sized tree with a conical head, growing on the more elevated parts of the mountain range; it furnishes edible seeds. The leaves, short and glaucous, like those of the Scotch fir, have deciduous sheaths; the cones have recurved scale-points like those of the cheer pine. *P. canariensis*, which forms forests on the mountains of Grand Canary and Teneriffe, growing at an elevation of 6000 ft., also belongs to this group. The leaves are long, lax, and of a bright green tint; the cone-scales are without spines; the trunk attains a large size, and yields good and durable timber. The beautiful Monterey pine, *P. insignis*, distinguished by the brilliant colour of its foliage, has the leaves in tufts of three of four; the lower cone-scales have recurved points. This fine pine has been planted in the south-west of England, but is scarcely hardy.

The pines with five leaves in each tuft have generally deciduous sheaths. The most important economic species is the well-known white pine, *P. Strobus*, from its large growth and abundance, as well as the soft even grain of its white wood, one of the most valuable of North American timber trees. The tree abounds from Canada to Georgia, but in the eastern states has been so long sought for by the lumberer that most of the old trees have long disappeared, and large white pine timber is now only found in quantity in the Canadian Dominion. Formerly Maine and Vermont were celebrated for the size of their pines, but few of these great trees now exist in New England. On a deep rich soil *P. Strobus* attains a height of 150 ft., and trunks without a branch are sometimes found 80 or 90 ft. long; in the earlier stages of growth it has a pyramidal form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The light bluish-green foliage is somewhat lax, very dense in young trees; the cones are long and rather curved, with thin smooth scales a little thickened at the apex, and generally more or less covered with exuding white resin; they are about 5 or 6 in. in length and 1½ to 2 in. broad; the male catkins are of a bluish tint; the cones ripen in the autumn of the second year. The wood of the white pine is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities are still exported, especially from Canada, its smooth easily-worked grain rendering it a favourite wood for the house-carpenter and joiner; it weighs about 28 ℔ per cubic foot. In England where it is generally known as the "Weymouth pine," it succeeds well on deep light soils when well drained; trees have attained occasionally a height of 100 ft. and upwards in British plantations; but it is apt to be infested with American blight (*Eriosoma*). In northern Germany it also grows well. The climate of Scotland

Piozzi; or the British Biographers, A Town Eclogue (1786). But though Miss Burney and some others held aloof, the Piozzis found plenty of friends when they returned to London in 1787. Piozzi died at Brynbella, a villa he had built on his wife's Carnarvonshire estate in 1809, and Mrs Piozzi gave up her Welsh property to her husband's son, and spent most of the rest of her life at Bath and Clifton. When long past seventy she took a fancy to William Augustus Conway, the actor. She retained her vivacity to the last, celebrating her 80th birthday by a ball to six or seven hundred people at Bath. She died at Clifton on the 2nd of May 1821.

From 1776 to 1809 she kept a note-book which she called "Thraliana." Her well-known poem of the "Three Warnings" is to be found in many popular collections. *Letters to and from the late Samuel Johnson* appeared in 1788; *Observations and Reflections made in the course of a Journey through France, Italy and Germany*, in 1789; and in 1801 she published *Retrospection; or a review of the most striking and important events, characters, and situations . . . which the last eighteen hundred years have presented to the view of mankind* (1801).

See *Letters and Literary Remains of Mrs Piozzi (Thrale), edited with notes and an Introductory Account of her Life and Writings by A. Hayward* (1861); *Piozziana; or Recollections of the late Mrs Piozzi by a Friend* (1833), the anonymous friend being Edward Mangin (1772–1852); L. B. Seeley, *Mrs Thrale, afterwards Mrs Piozzi . . .* (1891); and G. Birkbeck Hill, *Johnsonian Miscellanies* (1897). Also works noted in bibliography to JOHNSON, SAMUEL.

PIPE, a term used of a musical wind-instrument of tubular form, and hence of any cylindrical hollow tube. The original application of the term is to the musical instrument (see PIPE AND TABOR below), and the source is to be found in Lat. *pipare*, to chirp, of a bird. The general meaning of "pipe," in the sense of a tube for such purposes as carrying water, gas, sewage, &c., is treated under TUBE. Among specific uses of the word are those for the hollow stem of clay, wood or other material with a bowl at one end in which tobacco is smoked (see below); for the metal or wooden sound tubes in an organ (*q.v.*); and for various forms of cylindrical veins, hollows, channels, &c., in mining and geology. The Great Roll of the Exchequer was known as the "Pipe Roll"; this contained the various "pipes" or enrolled accounts of the sheriffs, &c., which were so called either from being sent in a cylindrical case or as resembling a pipe in shape when rolled (see RECORDS).

Tobacco Pipe.—The smoking of tobacco in pipes is a custom which prevailed in America for a period of unknown duration previous to the discovery of that continent by Columbus. The most ancient pipes of which remains exist have been found in mounds or tumuli called pipe mounds, principally in Ohio, Indiana, Illinois and Iowa. These mound pipes, which are carved in porphyry and other hard stones, are very uniform in type. The pipe, cut out of a single piece of stone, consists of a slightly convex platform or base, generally from 3 to 4 in. in length, and about an inch broad, with the bowl on the centre. A fine hole is pierced from one end of the platform to the bottom of the bowl, the opposite end being obviously for holding in the hand while the pipe is being smoked. In the commonest forms the bowl is a simple cylinder or urn (fig. 1), but in many cases remarkable artistic skill has been displayed in carving the bowls into miniature figures of birds, mammals, reptiles and human heads, often grotesque and fantastic, but always vigorously expressed (fig. 2). These mound or platform pipes with carved human and animal forms are objects of the highest ethnographic interest and importance, being among the most characteristic remains of the ancient inhabitants of the Mississippi valley. The wide area over which they, as well as remains of baked clay pipes, are found throughout the American continent testifies to the universal prevalence of smoking in the pre-Columbian era. Many of the ancient clay pipes found in Mexico, &c., are elaborately moulded and ornamented, while others show considerable similarity to the early clay pipes of Europe. Among the North-American Indian tribes the tobacco pipe occupies a position of peculiar symbolic significance in connexion with the superstitious rites and usages of the race. The calumet, peace pipe or medicine pipe, is an object of the most profound veneration, entrusted to the care of a highly honoured official, and produced and smoked with much ceremony only on occasions of great importance and solemnity. It is remarkable that, whilst the most ancient American pipes had no separate stem, it is the stem only of the medicine pipe which is the object of veneration among the Indians, the bowl used being a matter of indifference. The favourite material for Indian pipe bowls is the famous red pipe stone (catlinite), a fine-grained easily-worked stone of a rich red colour of the Côteau des Prairies, west of the Big Stone Lake in S. Dakota. The quarries were formerly neutral ground among the warring Indian tribes, many sacred traditions being associated with the locality and its product.

FIG. 1.—"Monitor" Pipe.

FIG. 2.—Heron Pipe.

It is disputed whether pipes for smoking were at all known in Europe previous to the discovery of America. That tobacco-smoking was unknown is certain; but pipes of iron, bronze and clay have been so frequently found associated with Roman remains and other antiquities as to lead many authorities to maintain that such pipes must have been anciently used for burning incense or for smoking aromatic herbs or hemp. Throughout Great Britain and Ireland small clay pipes are frequently dug up, in some instances associated with Roman relics. These are known amongst the people as elfin, fairy or Celtic pipes, and in some districts supernatural agencies have been called in to account for their existence. The elfin pipes have commonly flat broad heels in place of the sharp spur now found on clay pipes, and on that flat space the mark or initials of the maker is occasionally found. There is no reason to believe that these pipes are older than the 17th century. The introduction of the tobacco pipe into Europe is generally ascribed to Ralph Lane, first governor of Virginia, who in 1586 brought an Indian pipe to Sir Walter Raleigh, and taught that courtier how to use the implement. The pipe-makers of London became an incorporated body in 1619, and from England the other nations of Europe learned the art of making clay pipes.

The habit of smoking with pipes spread with incredible rapidity; and among the various peoples the pipe assumed special characteristics, and its modifications became the medium of conveying social, political and personal allusions, in many cases with no little artistic skill and humour. The pipe also became the object of much inventive ingenuity, and it varied as greatly in material as in form—wood, horn, bone, ivory, stone, precious and other metals, amber, glass, porcelain and, above all, clay being the materials employed in various forms. By degrees pipes of special form and material came to be associated with particular people, *e.g.* the elongated painted porcelain bowls and pendulous stem of the German peasantry, the red clay bowl and long cherry wood stem of the Turk, and the very small metallic bowl and cane stem of the Japanese, &c. Among other kinds of pipe which have been popular at various times are the "corn-cob," where the bowl is made of the cob of maize or Indian corn, and the "calabash" with the bowl of a small gourd. The "churchwarden" is a clay pipe with a slender stem, some 16 or 20 in. long. The most luxurious and elaborate form of pipe is the Persian *kalyún*, hookah or water tobacco pipe. This consists of three pieces, the head or bowl, the water bottle or base, and the snake or long flexible tube ending in the mouthpiece. The tobacco, which must be previously prepared by steeping in water, is placed in the head and lighted with live charcoal, a wooden stem passes from its bottom down into the water which fills the base, and the tube is fitted to a stem which ends in the bottle above the water. Thus the smoke is cooled and washed before it reaches the smoker by passing through the water in

species. *P. halepensis*, another Mediterranean form, is valued for its timber, which is white with a fine grain, and resinous products.

P. pinaster, the cluster pine or pinaster, is an important species from its vigorous growth in the sand-drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft. or more at the base, where, like most sand trees, it usually curves upward gradually, a form that enables the long tap-roots to withstand better the strain of the sea gale; when once established, the tree is rarely overthrown even on the loosest sand. The branches curve upwards like the stem, with their thick covering of long dark green leaves, giving a massive rounded outline to the tree; the ovate cones are from 4 to 6 in. long, of a light shining brown hue, with thick scales terminating in a pyramidal apex; they are arranged around the branches in the radiating clusters that give name to the tree. The pinaster grows naturally on sandy soils around the Mediterranean from Spain to the Levant. On the drift-sands of France, especially in the Gironde, forests have been formed mainly of this pine; the seeds, sown at first under proper shelter and protected by a thick growth of broom sown simultaneously, vegetate rapidly in the sea-sand, and the trees thus raised have, by their wind-drifted seed, covered much of the former desert of the Landes with an evergreen wood. These forests of pinaster, apart from the production of timber in a once treeless district, have a great economic value as a source of turpentine, which is largely obtained from the trees by a process analogous to that employed in its collection from *P. sylvestris*; the resin is yielded from May to the end of September, the cuts being renewed as the supply fails, until the tree is exhausted; the trunks are then felled and used in the manufacture of charcoal and lamp black; much tar and pitch is also obtained from these pinaster forests. In England the cluster-pine has been largely planted on sandy districts near the sea, and has become naturalized in Purbeck and other wild tracts in the southern counties, but the summer heat is too small to permit of its resinous products acquiring any value; the soft coarse wood, though perishable in the natural state, has been used for railway sleepers after saturation with creosote or preservative solutions.

P. Pinea is the stone pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nut-like seeds, which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid. The tree has been naturalized in many warm countries, even in China; in England it seldom attains any large size, as the deficient summer heat prevents the wood from maturing; but trees occur occasionally in plantations 20 or 30 ft. in height; the wood, though soft and deficient in the resin that gives durability to the timber of some species, is valued by the southern carpenter and cabinetmaker for its lightness, its fineness of grain, and the ease with which it is worked.

P. mitis, the yellow pine of the northern and middle states of America, is rather allied to the three-leaved section, but the leaves are mostly in pairs. It is a tree of large size, often attaining a height of 70 ft. and upwards, though rarely more than 2 ft. in diameter at the root; the lower branches spread horizontally, the upper, converging towards the trunk, give the tree somewhat the aspect of a spruce, hence it is called in some districts the "spruce-pine." The leaves are long, slender, and of a bluish-green hue; the pendant cones are about 1½ in. long, with a slender point to each scale. The yellow pine is one of the most important timber trees of the genus; the heart-wood being very durable is largely employed in ship-building and for house timber, being nearly equal to that of *P. sylvestris*; large quantities are exported to Britain under the name of "New York yellow pine"; the sapwood is perishable.

The three-leaved group includes several of the most valuable trees of America; among them is *P. rigida*, the pitch pine of the northern states, a tree of from 40 to 50 ft. in height with rugged trunk, occasionally 3 ft. in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. The wood is very hard and abounds with resin, but on swampy land is of inferior quality and of little value except for fuel, for which the pitch-pine is highly prized; on drier ground the grain is fine from the numerous knots. Large quantities of tar and pitch are obtained from this species. The tree is one of the few that will flourish in salt-marshes.

P. palustris (or *P. australis*) is the "Georgia pitch pine," or yellow pine of the southern states; it abounds on the sandy soils that cover so much of Georgia, the Carolinas, and Florida, and on those dry lands attains its highest perfection, though occasionally abundant on moist ground, whence its name. The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk furnishes the most valued pine timber of the states; close-grained and resinous, it is very durable and polishes well; it is largely employed in American shipyards, and immense quantities are exported, especially to Britain and the West Indies. This tree yields an abundant supply of tar and turpentine of good quality, which products are collected and manufactured in the "pine-barrens" on a large scale.

P. Taeda, the "loblolly pine" of the backwoodsman, a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern states, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 or 90 ft. high, having sometimes a girth of 6 or 8 ft., with a broad spreading head; the leaves are rather long and of a light green tint, the cones generally in pairs, the scales terminating in a sharp incurved prickle. The timber of this pine is indifferent, but the forests of it are of importance from the quantity of turpentine they yield; the trees also furnish much firewood of good quality.

P. ponderosa, the yellow pine of the Pacific coast of America, belongs to this section; it is a fine timber tree deserving of notice from the extreme density of its wood, which barely floats in water; it abounds in some parts of the western range of the Rocky Mountains, and is the most widely distributed pine tree of the mountain forests of western North America. The leaves are very long and twisted, the small oval cones armed with recurved prickles; the tree is said to be of rapid growth. In Oregon and California several large pines of this group are found. *P. Coulteri* or *macrocarpa*, is remarkable for its enormous cones (sometimes a foot long, 6 in. in diameter, and weighing more than 4 ℔); the scales end in long hooked points curving upwards; the leaves are long, rigid, and glaucous in hue. Nearly related to this is *P. Sabiniana*, the nut-pine of California, the cones of which are 7 to 9 in. long and 5 to 6 in. in diameter, also with hooked scales; the large nut-like seeds are eaten by the Indians; the tree is one of the largest of the section, sometimes attaining a height of 120 ft. and upwards, while trunks have been found, it is said, 10 or 12 ft. in diameter. *P. longifolia*, a Himalayan species, is remarkable for the great length of its lax slender leaves, of a grass-green tint; the cones have the points of the scales recurved. It is known in India as the "cheer pine"; the wood is good, resinous, and moderately durable; the tree is common on the foot-hills of the Himalayas. *P. Gerardiana*, a north-west Himalayan species, is a medium-sized tree with a conical head, growing on the more elevated parts of the mountain range; it furnishes edible seeds. The leaves, short and glaucous, like those of the Scotch fir, have deciduous sheaths; the cones have recurved scale-points like those of the cheer pine. *P. canariensis*, which forms forests on the mountains of Grand Canary and Teneriffe, growing at an elevation of 6000 ft., also belongs to this group. The leaves are long, lax, and of a bright green tint; the cone-scales are without spines; the trunk attains a large size, and yields good and durable timber. The beautiful Monterey pine, *P. insignis*, distinguished by the brilliant colour of its foliage, has the leaves in tufts of three of four; the lower cone-scales have recurved points. This fine pine has been planted in the south-west of England, but is scarcely hardy.

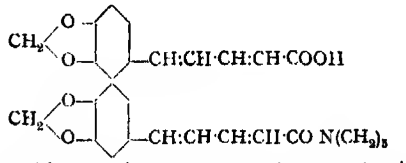
The pines with five leaves in each tuft have generally deciduous sheaths. The most important economic species is the well-known white pine, *P. Strobus*, from its large growth and abundance, as well as the soft even grain of its white wood, one of the most valuable of North American timber trees. The tree abounds from Canada to Georgia, but in the eastern states has been so long sought for by the lumberer that most of the old trees have long disappeared, and large white pine timber is now only found in quantity in the Canadian Dominion. Formerly Maine and Vermont were celebrated for the size of their pines, but few of these great trees now exist in New England. On a deep rich soil *P. Strobus* attains a height of 150 ft., and trunks without a branch are sometimes found 80 or 90 ft. long; in the earlier stages of growth it has a pyramidal form, in open glades the lower boughs often touching the ground, but in old age it acquires a wide almost cedar-like top. The light bluish-green foliage is somewhat lax, very dense in young trees; the cones are long and rather curved, with thin smooth scales a little thickened at the apex, and generally more or less covered with exuding white resin; they are about 5 or 6 in. in length and 1½ to 2 in. broad; the male catkins are of a bluish tint; the cones ripen in the autumn of the second year. The wood of the white pine is durable for indoor use, especially when protected by paint, but when exposed to moist air it rapidly decays, and it is very liable to dry rot; it is said to be best when grown on sandy soils. Immense quantities are still exported, especially from Canada, its smooth easily-worked grain rendering it a favourite wood for the house-carpenter and joiner; it weighs about 28 ℔ per cubic foot. In England where it is generally known as the "Weymouth pine," it succeeds well on deep light soils when well drained; trees have attained occasionally a height of 100 ft. and upwards in British plantations; but it is apt to be infested with American blight (*Eriosoma*). In northern Germany it also grows well. The climate of Scotland

own. He belonged to the school of Benedict Oxenstjerna and was therefore an avowed advocate of a pacific policy. He protested in vain against nearly all the military ventures of Charles XII., *e.g.* the War of Deposition against Augustus of Saxony and Poland, the invasion of Saxony, the raid into the Ukraine. Again and again he insisted that the pacific overtures of Peter the Great should at least be fairly considered, but his master was always immovable. Piper's career came to an end at Poltava (1709), where he was among the prisoners. The last years of his life were spent in exile in Russia. He died at Schlüsselburg on the 29th of May 1716.

See W. L. Svedelius, *Count Carl Piper* (Stockholm, 1869). (R. N. B.)

PIPERAZIN, a substance formed by the action of sodium glycol on ethylene-diamine hydrochloride, consisting of small alkaline deliquescent crystals with a saline taste and soluble in water. It was originally introduced into medicine as a solvent for uric acid. When taken into the body the drug is partly oxidized and partly eliminated unchanged. Outside the body piperazin has a remarkable power of dissolving uric acid and producing a soluble urate, but in clinical experience it has not proved equally successful. Lycetol, lysidine and sidonal are bodies having similar action.

PIPERINE, $C_{17}H_{19}NO_3$, an alkaloid found in the fruits of *Piper nigrum* and *P. longum*. It forms white prisms, which melt at 128°–219°. It is almost insoluble in water, but readily soluble in alcohol and ether. It is a very weak base, salts being only formed with mineral acids, and these are dissociated by water. Alcoholic potash decomposes it into piperidine, $C_5H_{11}N$, and piperic acid, $C_{12}H_{10}O_4$. The constitution of piperic acid was elucidated by R. Fittig and his pupils (*Ann.*, vols. 152, 159, 168, 216, 227) and shown to be (1). Piperine consequently is (2).



(1)

(2)

Oxidation with potassium permanganate converts piperic acid into piperonal, $C_8H_6O_3$, and piperonylic acid, $C_8H_6O_4$. The latter when heated with hydrochloric acid to 170°, or water to 200°, separates carbon with the formation of protocatechuic acid, 1·2-dioxy-3-benzoic acid, $C_6H_3(OH)_2COOH$. Conversely, by heating protocatechuic acid with potash and methylene iodide, piperonylic acid was regained. These results show that piperonylic acid is the methylene ether of protocatechuic acid. Piperonal (*q.v.*) is the corresponding aldehyde. Piperic acid differs from piperonylic acid by the group C_4H_4, and it was apparent that these carbon atoms must be attached to the carbon atom which appears in the carboxyl group of piperonylic acid, for if they were directly attached to the benzene ring polycarboxylic acids would result in oxidation. The above formula for piperic acid was confirmed by its synthesis by A. Ladenburg and M. Scholtz (*Ber.*, 1894, 27, p. 2958) from piperonyl acrolein (the condensation product of piperonal and acetaldehyde) and acetic acid. The synthesis of piperine follows from the interaction of piperyl chloride (formed from piperic acid and phosphorus pentachloride) and piperidine (L. Rügheimer, *Ber.*, 1882, 15, p. 1390).

PIPERNO (anc. *Privernum*), a town of the province of Rome, Italy, 61 m. S.E. of Rome by rail. Pop. (1901), 6736. The medieval town was founded in the 10th century (?) on a hill 490 ft. above sea-level, by refugees from the Roman town of Privernum, lower down (118 ft. above sea-level) on the highroad, 1½ m. to the north, at the mouth of a low pass leading through the Volscian mountains to the valley of the Sacco. Here are remains of an arch crossing the road and other ruins (mostly buried) of the Roman period; but the remains above ground are largely medieval. It is improbable, however, that the ancient Volscian town should have occupied so easily accessible a site; it is not unlikely that it stood on the site occupied by the medieval and modern town, but there is no proof of this. Privernum was a Volscian town, and took up arms against Rome after the foundation of a Latin colony at Setia in 382 B.C. It was finally captured in 329 B.C. and eleven years later the tribus Oufentina was founded, taking its name from the river Oufens (mod. Uffente) in the territory of Privernum. Little is known of it subsequently. The medieval town has a picturesque piazza, with a Gothic cathedral (1283), which preserves a fine porch, though the interior was modernized in 1782; a Gothic palazzo pubblico; and other Gothic churches exist in the town. Polygonal terrace walls of the Roman or pre-Roman period exist at various places in the vicinity (G. B. Giovenale and L. Mariani in *Notizie degli Scavi*, 1899, 88). (T. As.)

PIPERONAL (heliotropine, protocatechuic aldehyde methylene ether), $C_8H_6O_3$, an aromatic aldehyde. It is prepared by oxidizing piperic acid with potassium permanganate (R. Fittig, *Ann.*, 1869, 152, p. 35); by condensing methylene iodide with protocatechuic aldehyde (R. Wegscheider, *Monats.*, 1893, 14, p. 388); or by oxidizing isosafrol with chromic acid. It forms long colourless crystals which melt at 37° C. and boil at 263° C. It has an agreeable smell, resembling that of heliotrope, and is much used in perfumery. It is only slightly soluble in cold water, but is readily soluble in alcohol and in ether. When heated with dilute hydrochloric acid to 200° C. it yields protocatechuic aldehyde, $C_7H_6O_3$, and carbon. It readily combines with sodium bisulphite and with various bases (ammonia, aniline, methylamine, &c.).

PIPIT (cognate with the Lat. *Pipio*; see PIGEON), the name applied by ornithologists to a group of birds having a great resemblance both in habits and appearance to the larks (*q.v.*). They differ however from larks in several important characters, and, having been first separated to form the genus *Anthus*, which has since been much broken up, are now generally associated with the wagtails (*q.v.*) in the Passerine family *Motacillidae*. Pipits, of which over fifty species have been described, occur in almost all parts of the world, but in North America are represented by only two species—*Neocorys spraguii*, the prairie-lark of the north-western plains, and *Anthus ludovicianus*, the American titlark, which last is very nearly allied to the so-called water-pipit of Europe, *A. spipoletta*. To most English readers the best known species of pipit is the titlark or meadow-pipit, *A. pratensis*, a bird too common to need description, and abundant on pastures, moors, and uncultivated districts generally; but in some localities the tree-pipit, *A. trivialis*, or *A. arboreus* of some authors, takes its place, and where it does so it usually attracts attention by its loud song, which is not unlike that of a canary, but delivered (as appears to be the habit of all the pipits) on the wing and during a short circuitous flight. Another species, the rock-lark, *A. obscurus*, scarcely ever leaves the sea-coast and is found almost all round the British Islands. The South African genus *Macronyx*, remarkable for the extreme length of its hind claw, is generally placed among the pipits, but differs from all the rest in its brighter coloration, which has a curious resemblance to the American genus *Sturnella* (see ICTERUS), though the bird is certainly not allied thereto. (A. N.)

PIPPIN, or PEPIN, the name of three members of the Carolingian family.

PIPPIN I. (d. 640), incorrectly called Pippin of Landen, was mayor of the palace to the youthful Dagobert I., whom Clotaire II. had placed over the kingdom of Austrasia. He was disgraced when Dagobert became sole king in 629, and had to seek refuge in Aquitaine. Returning at Dagobert's death (639), he governed Austrasia in Sigebert's name, but died in the following year.

PIPPIN II. (d. 714), incorrectly called Pippin of Herstal, was son of Adalgiselus (son of Arnulf, bishop of Metz) by a daughter of Pippin I., called in later documents Begga. Towards 678 he placed himself at the head of the great nobles in Austrasia to combat Ebroïn, the mayor of the palace, and Neustria. After some reverses he gained a great victory after Ebroïn's death at the battle of Tertry, not far from St Quentin. This victory made Pippin almost entire master of Gaul. He appointed one of his sons mayor of the palace of Neustria, reserving for another of his sons the mayoralty of Austrasia. He made war

on the Frisians and defeated their duke Radbod; and part of this people became converts to Christianity. He also defeated Willari, the duke of the Alamanni, and subdued his country. The Bavarians, too, recognized the Frankish suzerainty. The plans he had formed for reforming the church and convoking councils were interrupted by his death, which took place on the 16th of December 714.

PIPPIN III. (d. 768), the Short,[1] was son of Charles Martel. Before his death in 741 Charles Martel had divided the Frankish kingdom between his two sons, Carloman and Pippin, giving Carloman the eastern part and Pippin the western. Since 737 there had been no king in the Frankish realm; in the diplomas the two brothers bear the title of *majores palatii*, while the chroniclers call them simply *principes*. In 743, however, the mayors decided to appoint a king in the person of Childeric III., who was apparently connected with the Merovingian family. But Childeric was a mere figure-head, and had no power. The two brothers presided over the tribunals, convoked the councils at which the Frankish Church was reformed, assembled the host and made war, jointly defeating and subduing Duke Hunald of Aquitaine. In 747 Carloman unexpectedly abdicated, became a monk, and retired to a monastery near Rome, subsequently founding on Mt Soracte the monastery of St Silvester. From the time of the abdication Pippin was sole master; and in 751, after consulting Pope Zacharias, he took the title of king and removed the feeble Childeric to a monastery. He then got himself crowned by St Boniface, a ceremony which was new to France and which gave the sovereign immense prestige; henceforth the king of the Franks called himself *Gratia Dei rex Francorum*. Pippin's reign is marked by many important events. He received in France a personal visit from Pope Stephen II., who conferred on him the title of Patrician of the Romans and recrowned him. In return for these honours Pippin, at the appeal of the pope, made two expeditions into Italy, in 754 and 756; and he became the veritable creator of the papal state by conferring on the pope the exarchate of Ravenna, which he had wrested from Aistulf, the king of the Lombards. Pippin took Septimania from the Arabs, and after a stubborn war of nearly eight years' duration (760–68) succeeded in taking Aquitaine from its duke, Waifer. He also intervened in Germany, where he forced the duke of Bavaria, Tassilo, to become his vassal. In 763, however, Tassilo abandoned Pippin during an expedition against Aquitaine. Pippin made several expeditions against the Saxons, but failed to subdue them. He entered into relations with the Eastern Empire, exchanging ambassadors with the emperor Constantine Copronymus. During Pippin's reign Frankish institutions underwent some modification. The Frankish assemblies, previously held in the month of March (*champs de mars*), but under Pippin deferred to May (*champs de mai*), came to be more numerous, and served the king of the Franks as a means of receiving the gifts of his subjects and of promulgating his capitularies. At the head of the administration was placed the arch-chaplain, and an ecclesiastical chancellor was substituted for the ancient *referendarius*. Ecclesiastical reform was continued under Pippin, Bishop Chrodegans of Metz uniting the clergy of Metz in a common life and creating canons (see CANON). Pippin died on the 24th of September 768 at St Denis, leaving two sons, Charles (Charlemagne) and Carloman.

PIPRĀWA, a village on the Birdpur estate in the Basti district, United Provinces, India. It lies on the Uska-Nepal road at mile 19·75; and about half a mile south of the boundary pillar numbered 44 on the frontier line between British and Nepalese territory. The village is celebrated as the site of the following discovery:—

In 1896 interest having been aroused by the discovery, only twelve miles away, of the Buddha's birthplace (see LUMBINI), William Peppé, then resident manager of the Birdpur estate, opened a ruined tope or burial mound situate at Piprāwa, but nothing of importance was found. In January 1897 he carried the work of excavation farther. A well, 10 ft. sq., was dug down the centre of the mound. After digging through 18 ft. of solid brickwork set in clay a massive stone coffer was found lying due magnetic north and south. Its dimensions were, 4 ft. 4 in. by 2 ft. 8½ in. and 2 ft. 2¼ in. high. The stone lid of the coffer was split into four pieces; but the coffer remained perfectly closed, so accurately was the lid fitted into flanges on the sides of the box. The pieces were thus firmly held in their place, and the contents of the coffer were found intact. These consisted of five vessels, two vases, a bowl and a casket being made of steatite, and the fifth, also a bowl, of crystal. All these vessels are beautifully worked, the crystal bowl especially, with its fish-shaped cover handle, being as a work of art of high merit.[2] The coffer is of fine hard sandstone of superior quality, and has been hollowed out, at the cost of vast labour and expense, from a solid block of rock. Peppé calculates its weight, lid included, at 1537 lb. It is only the great solidity of this coffer which has preserved the contents. A cover of one of the vases was found dislodged and lying on the bottom of the stone coffer. As this cover fits very well it must have required a quite violent shock to remove it. This was almost certainly the shock of an earthquake, and the same shock probably caused the split in the stone lid of the coffer itself.

The vessels contained a dark dust, apparently disintegrated ashes, small pieces of bone, and a number of small pieces of jewelry in gold, silver, white and red cornelian, amethyst, topaz, garnet, coral and crystal. Most of these are perforated for mounting on threads or wires, and had been, no doubt, originally connected together to form one or more of the elaborate girdles, necklaces and breast ornaments then worn by the women.[3] On the bottom of the stone box there was similar dust, pieces of bone and jewelry, and also remains of what had been vessels of wood. The knob forming the handle of one of these wooden receptacles was still distinguishable. The total quantity of scraps of bone may have amounted to a wineglassful.

An inscription ran round one of the steatite vases just below the lid.[4] The words mean: *This shrine for ashes of the Buddha, the Exalted One, is the pious work of the Sakiyas, his brethren, associated with their sisters, and their children, and their wives.* The thirteen words, in a local dialect of Pali, are written in very ancient characters, and are the oldest inscription as yet discovered in India. Twelve out of the thirteen are well-known words, the interpretation of which is not open to doubt. One word, rendered above by "pious work," has not been found elsewhere, and its derivation is open to discussion. The explanation here adopted as most probable was put forward by Professor Pischel of Berlin.[5] The phrase "pious work" probably had a precise technical connotation like the English "benefaction."

The monument must have been of imposing appearance. The diameter (on the ground level) of the dome is 116 ft. For 8 ft. from the summit of the ruin it was not possible to trace the outline. At that point the outer wall, if one may so call it, of the solid dome could be traced, and had a diameter of 68 ft. The dome, therefore, sloped inwards 1 ft. for every 3 ft. in height, in other words, it was, like all the most ancient of these artificial burial domes in India, a shallow dome, and cannot have been more than about 35 ft. high exclusive of the ornament or "tee" on the summit. We have in bas-reliefs of the 3rd century representations of what these ornaments were like—small

[1] A surname given to Pippin III. on the strength of a legendary anecdote related by the monk of St Gall.

[2] An illustration from a photograph is given in Rhys Davids' *Buddhist India*, p. 131.

[3] For figures of the jewelry found see the plate in Mr Peppé's article, reproduced in Rhys Davids' *Buddhist India*, p. 89. For the jewelry of the time, ibid., pp. 90, 91.

[5] *Zeitschrift der deutschen morgenländischen Gesellschaft*, lvi. 157.

square erections, like a shrine or small temple, surmounted by a canopy called from its shape a T. They were then more than a third of the height of the dome itself. The total height of this Sākiya tope will therefore have been approximately a little under 50 ft. It was probably surrounded by a carved wooden railing, but this has long since disappeared.

All such monuments hitherto discovered in India were put up in honour of some religious teacher, not in memory of royal persons, generous benefactors, politicians, or soldiers or private persons, however distinguished. And we need have no hesitation in accepting this as a monument put up over a portion of the ashes from the funeral pyre of Gotama the Buddha. The account of the death and cremation of the Buddha, preserved in the Buddhist canon, states that one-eighth portion of the ashes was presented to the Sākiya clan, and that they built a *thūpa*, or memorial mound, over it.[1]

Mr Peppé presented the coffer and vases with specimens of the jewelry to the museum at Calcutta where they still are. He also gave specimens of the trinkets to the Asiatic Society in London.

Peppé's original article is in the *Journal of the Royal Asiatic Society* for 1898, pp. 573 sqq. Comments upon it, one or two of them sceptical, are in the same journal 1898, pp. 579, 588, 387, 868; 1899, p. 425; 1901, p. 398; 1905, p. 679; 1906, pp. 149 sqq. See also A. Barth, *Comptes rendues de l'academie des inscriptions* (1898), xxvi., 147, 233; Sylvain Levy, *Journal des savants* (1905) pp. 540 sqq.; and R. Pischel and Rhys Davids as quoted above. (T. W. R. D.)

PIQUA, a city of Miami county, Ohio, U.S.A., on the Miami River and the Miami & Erie Canal, 73 m. W. by N. of Columbus. Pop. (1890), 9090; (1900), 12,172, of whom 901 were foreign-born and 487 were negroes; (1910, census), 13,388. It is served by the Pittsburg, Cincinnati, Chicago & St Louis, and the Cincinnati, Hamilton & Dayton railways, and by inter-urban electric lines to Lima, Dayton and Covington. It has a park, a public library and a public hospital. There are quarries of blue limestone in the vicinity. The city has various manufactures, the factory products being valued in 1905 at $4,035,706. The municipality owns and operates its waterworks. On or near the site of Piqua was one of the principal villages of the Chillicothe division of the Shawnee tribe; the village also was called Chillicothe. It was destroyed by George Rogers Clark in 1782. A town was laid out here in 1809 under the name of Washington, and the present name, that of another division of the Shawnee tribe, was substituted in 1823. Piqua was chartered as a city in 1846. During the French and Indian War, in 1763, a battle was fought in this vicinity chiefly between the Miamis, Wyandots, Ottawas and other Indian allies of the French, and the Delawares, Shawnees, Cherokees, Catawbas and other Indian allies of the English, the English allies making an unsuccessful attempt to drive the French allies from their fortified position, Fort Piqua.

See Henry Howe, *Historical Collections of Ohio* (Columbus, 1891).

PIQUET, a game at cards, probably a development of *ronfa*, a game mentioned by Berni in 1526; *la ronfle* (included in Rabelais's list, *c.* 1530) may be regarded as the same game. The point at piquet was anciently called *ronfle*. The Spanish name of the game was *cientos* (*centum*, a hundred). Piquet was played in England under the name of *cent*, or *sant*, probably as early as 1550 (contemporaneously with the marriage of Mary to Philip of Spain). About the middle of the 17th century (shortly after the marriage of Charles I. to Henrietta Maria of France) the name cent was dropped in England, and the French equivalent, piquet, adopted. It is played by two persons, with a pack of thirty-two cards—the sixes, fives, fours, threes and twos being thrown out from a complete pack. At one time the *partie* was the best of five games of a hundred up (a player not obtaining fifty losing a double game). But now the *partie* is generally determined in six hands, the player making the largest aggregate score being the winner. The number of points won is the difference between the two scores, with a hundred added for the game. If, however, the loser fails to make a hundred in six hands, the number of points won is the sum of the two scores, with a hundred for the game. Piquet played in this way is called *Rubicon Piquet.*

The dealer deals twelve cards to his adversary and twelve to himself, two at a time, or three at a time. He then places the eight undealt cards, called the "stock," face downwards on the table, the top five being for the elder hand (non-dealer) to take from first in exchange for his own. The players now look at their hands, and *carte blanche* (see later) having been declared, if there is one, put out (without showing them) such cards as they deem advisable in order to improve their hands, and take in an equivalent number from the stock. Each player must discard at least one card. If the elder hand discards less than the five he is entitled to, he must state how many he leaves. He is entitled to look at the cards he leaves, replacing them face downwards on the top of the stock. The younger hand then makes the exchange from the remainder of the stock. If the elder hand leaves any of the top five, the younger may exchange as many as remain in the stock, discarding an equal number. If the younger hand leaves any cards, he announces the number left. He may look at the cards he leaves. If he looks at them he must show them to the elder hand, after the elder has named the suit he will lead first, or has led a card.

If the younger hand elects not to look at the cards left the elder cannot see them. The younger hand must make his election before he plays to the card first led, or, if so required, after the dealer has named the suit he will first lead. Each player may examine his own discard at any time during the hand; but he must keep it separate from his other cards.

The elder hand next makes a declaration of what he has in his hand.

The "point" must be called first or the right to call it is lost. It is scored by the player who announces the suit of greatest strength, valued thus: ace 11; court cards, 10 each; other cards, the number of pips on each. Thus if the elder hand's best suit is ace, king, knave, nine, eight, he calls "five cards." If the younger hand has no suit of five cards, he says "good." The elder hand then says "in spades," or whatever the suit may be, or shows his point face upwards. If the younger hand has a suit of more than five cards, he says "not good." If the younger hand has also five cards, he says "equal" or "what do they make?" when the elder calls "forty-eight" (or "making eight," short for forty-eight). The younger must not inquire what the point makes unless he has an equal number of cards. If the younger hand's five cards make less than forty-eight he says "good"; if exactly forty-eight, he says "equal"; if more than forty-eight he says "not good." The player whose point is good reckons one for each card of it; if the points are equal neither player scores for point.

"Sequences" are usually called next, the elder hand stating what his best sequence is, and the younger saying, "good," "equal," or "not good," as in the case of the point. Any three or more consecutive cards of the same suit held in hand constitute a sequence. The order of the cards is as follows: ace (highest), king, queen, knave, ten, nine, eight, seven (lowest). A sequence of three cards is called a "tierce"; of four, a "quart"; of five, a "quint"; of six, a "sixième"; of seven, a "septième"; of eight, a "huitième." A tierce of ace, king, queen is called a "tierce major"; a tierce of king, queen, knave is called a "tierce to a king" (and so on for other intermediate sequences according to the card which heads them); a tierce of nine, eight, seven is called a "tierce minor." Sequences of four or more cards follow the same nomenclature; *e.g.* ace, king, queen, knave is a quart major; knave, ten, nine, eight, is a quart to a knave; and so on. A sequence of a greater number of cards is good against a sequence of a smaller number; thus, a quart minor is good against a tierce major. As between sequences containing the same number of cards, the one headed by the highest card is good; thus, a quart to a queen is good against a quart to a knave. Only identical sequences can be equal. The player whose sequence is good reckons one for each card of it, and ten in addition for quints or higher sequences. Thus a tierce counts three; a quart, four; a quint, fifteen; a sixième, sixteen; and so on. If the elder hand's sequence is good, he names the suit, or shows it face upwards. If the highest sequence (or the sequence first called) is good, all lower sequences can be reckoned, notwithstanding that the adversary has a sequence of intermediate value. For example, A has a quart to a queen (good,) and a tierce minor. He calls and reckons seven, notwithstanding that B has a quart to a knave. B's quart counts nothing. If the highest sequence is equal, neither player scores anything for sequence, even though one player may hold a second sequence of equal or inferior value.

"Quatorzes" and "trios" are the next calls. "Quatorzes" are composed of four aces, four kings, four queens, four knaves, or four tens, in order of value; "trios" of three of any of these. A quatorze, if good, reckons fourteen; a trio, if good, reckons three; one that is good establishes any smaller quatorzes or trios in his hand.

When the elder hand has done calling he leads a card. Before

[1] Translated in Rhys Davids' *Buddhist Suttas* (Oxford, 1881).

on the Frisians and defeated their duke Radbod; and part of this people became converts to Christianity. He also defeated Willari, the duke of the Alamanni, and subdued his country. The Bavarians, too, recognized the Frankish suzerainty. The plans he had formed for reforming the church and convoking councils were interrupted by his death, which took place on the 16th of December 714.

Pippin III. (d. 768), the Short,[1] was son of Charles Martel. Before his death in 741 Charles Martel had divided the Frankish kingdom between his two sons, Carloman and Pippin, giving Carloman the eastern part and Pippin the western. Since 737 there had been no king in the Frankish realm; in the diplomas the two brothers bear the title of *majores palatii*, while the chroniclers call them simply *principes*. In 743, however, the mayors decided to appoint a king in the person of Childeric III., who was apparently connected with the Merovingian family. But Childeric was a mere figure-head, and had no power. The two brothers presided over the tribunals, convoked the councils at which the Frankish Church was reformed, assembled the host and made war, jointly defeating and subduing Duke Hunald of Aquitaine. In 747 Carloman unexpectedly abdicated, became a monk, and retired to a monastery near Rome, subsequently founding on Mt Soracte the monastery of St Silvester. From the time of the abdication Pippin was sole master; and in 751, after consulting Pope Zacharias, he took the title of king and removed the feeble Childeric to a monastery. He then got himself crowned by St Boniface, a ceremony which was new to France and which gave the sovereign immense prestige; henceforth the king of the Franks called himself *Gratia Dei rex Francorum*. Pippin's reign is marked by many important events. He received in France a personal visit from Pope Stephen II., who conferred on him the title of Patrician of the Romans and recrowned him. In return for these honours Pippin, at the appeal of the pope, made two expeditions into Italy, in 754 and 756; and he became the veritable creator of the papal state by conferring on the pope the exarchate of Ravenna, which he had wrested from Aistulf, the king of the Lombards. Pippin took Septimania from the Arabs, and after a stubborn war of nearly eight years' duration (760–68) succeeded in taking Aquitaine from its duke, Waifer. He also intervened in Germany, where he forced the duke of Bavaria, Tassilo, to become his vassal. In 763, however, Tassilo abandoned Pippin during an expedition against Aquitaine. Pippin made several expeditions against the Saxons, but failed to subdue them. He entered into relations with the Eastern Empire, exchanging ambassadors with the emperor Constantine Copronymus. During Pippin's reign Frankish institutions underwent some modification. The Frankish assemblies, previously held in the month of March (*champs de mars*), but under Pippin deferred to May (*champs de mai*), came to be more numerous, and served the king of the Franks as a means of receiving the gifts of his subjects and of promulgating his capitularies. At the head of the administration was placed the arch-chaplain, and an ecclesiastical chancellor was substituted for the ancient *referendarius*. Ecclesiastical reform was continued under Pippin, Bishop Chrodegans of Metz uniting the clergy of Metz in a common life and creating canons (see Canon). Pippin died on the 24th of September 768 at St Denis, leaving two sons, Charles (Charlemagne) and Carloman.

PIPRÂWA, a village on the Birdpur estate in the Basti district, United Provinces, India. It lies on the Uska-Nepal road at mile 19·75; and about half a mile south of the boundary pillar numbered 44 on the frontier line between British and Nepalese territory. The village is celebrated as the site of the following discovery:—

In 1896 interest having been aroused by the discovery, only twelve miles away, of the Buddha's birthplace (see Lumbini), William Peppé, then resident manager of the Birdpur estate, opened a ruined tope or burial mound situate at Piprâwa, but nothing of importance was found. In January 1897 he carried the work of excavation farther. A well, 10 ft. sq., was dug down the centre of the mound. After digging through 18 ft. of solid brickwork set in clay a massive stone coffer was found lying due magnetic north and south. Its dimensions were, 4 ft. 4 in. by 2 ft. 8½ in. and 2 ft. 2¼ in. high. The stone lid of the coffer was split into four pieces; but the coffer remained perfectly closed, so accurately was the lid fitted into flanges on the sides of the box. The pieces were thus firmly held in their place, and the contents of the coffer were found intact. These consisted of five vessels, two vases, a bowl and a casket being made of steatite, and the fifth, also a bowl, of crystal. All these vessels are beautifully worked, the crystal bowl especially, with its fish-shaped cover handle, being as a work of art of high merit.[2] The coffer is of fine hard sandstone of superior quality, and has been hollowed out, at the cost of vast labour and expense, from a solid block of rock. Peppé calculates its weight, lid included, at 1537 lb. It is only the great solidity of this coffer which has preserved the contents. A cover of one of the vases was found dislodged and lying on the bottom of the stone coffer. As this cover fits very well it must have required a quite violent shock to remove it. This was almost certainly the shock of an earthquake, and the same shock probably caused the split in the stone lid of the coffer itself.

The vessels contained a dark dust, apparently disintegrated ashes, small pieces of bone, and a number of small pieces of jewelry in gold, silver, white and red cornelian, amethyst, topaz, garnet, coral and crystal. Most of these are perforated for mounting on threads or wires, and had been, no doubt, originally connected together to form one or more of the elaborate girdles, necklaces and breast ornaments then worn by the women.[3] On the bottom of the stone box there was similar dust, pieces of bone and jewelry, and also remains of what had been vessels of wood. The knob forming the handle of one of these wooden receptacles was still distinguishable. The total quantity of scraps of bone may have amounted to a wineglassful.

An inscription ran round one of the steatite vases just below the lid.[4] The words mean: *This shrine for ashes of the Buddha, the Exalted One, is the pious work of the Sakiyas, his brethren, associated with their sisters, and their children, and their wives.* The thirteen words, in a local dialect of Pali, are written in very ancient characters, and are the oldest inscription as yet discovered in India. Twelve out of the thirteen are well-known words, the interpretation of which is not open to doubt. One word, rendered above by "pious work," has not been found elsewhere, and its derivation is open to discussion. The explanation here adopted as most probable was put forward by Professor Pischel of Berlin.[5] The phrase "pious work" probably had a precise technical connotation like the English "benefaction."

The monument must have been of imposing appearance. The diameter (on the ground level) of the dome is 116 ft. For 8 ft. from the summit of the ruin it was not possible to trace the outline. At that point the outer wall, if one may so call it, of the solid dome could be traced, and had a diameter of 68 ft. The dome, therefore, sloped inwards 1 ft. for every 3 ft. in height, in other words, it was, like all the most ancient of these artificial burial domes in India, a shallow dome, and cannot have been more than about 35 ft. high exclusive of the ornament or "tee" on the summit. We have in bas-reliefs of the 3rd century representations of what these ornaments were like—small

[1] A surname given to Pippin III. on the strength of a legendary anecdote related by the monk of St Gall.

must be brought before the proper tribunal and dealt with according to law.

Piracy has been dealt with in a large number of English statutes, from 1536 down to the Territorial Waters Jurisdiction Act 1878 (41 & 42 Vict. c. 73), which provided for the maintenance of the existing jurisdiction for the trial of "any act of piracy as defined by the law of nations."

During the Spanish-American War the Spanish government issued (1898) a decree declaring that "captains, masters and officers of vessels, which, as well as two-thirds of their crew, are not American, captured while committing acts of war against Spain, even if they are provided with letters of marque issued by the United States" would be regarded and judged as pirates. This was not in accordance with the international practice on the subject. A public ship or one which is entitled to fly the flag of a belligerent and navigates under the cover of state papers, by the very sense of the term, is not a pirate. Again, during the Russo-Japanese War, the word "piracy" was freely applied in British newspapers to the seizure of the "Malacca" and other vessels held up by the "Peterburg" and "Smolensk," two cruisers belonging to the Russian Black Sea volunteer fleet, which in July 1904 passed as merchantmen through the Bosporus and Dardanelles and were transformed to their real character on the open sea. The application of the term in this case was equally inaccurate.

The conversion of merchant into war ships was one of the subjects dealt with by the second Hague Conference (1907), but it was agreed that "the question of the place where such conversion is effected remains outside the scope of the agreement."

Piracy is essentially a crime under international law, and although any state may apply its penalties to its own subjects by analogy, as was done by Great Britain and the United States in connexion with the repression of the slave trade, they cannot be lawfully applied to subjects of other states. (T. Ba.)

Historical Sketch.—It has at all times been more difficult to enforce good order on the sea than on the land; or perhaps we ought to say that the establishment of law and order on the sea has in all ages of the world's history followed, but has not accompanied, and has still less preceded, the creation of a good police on the land. The sea robber, or pirate, cannot make a profit from any part of his booty except the food which he consumes, or the vessels which he may use, unless he can find a market. But so long as he is sure that he will somewhere meet a purchaser for the goods he has taken by violence, he has every encouragement to pursue his trade. Therefore from the times described in the *Odyssey*, down to the days when Sir Henry Keppel sailed in H.M.S. "Dido" to suppress the pirates of Borneo, and when Rajah Brooke of Sarawak co-operated with him on land, we find that the prevalence of piracy and the suppression of it have been closely dependent on the efforts made to rout it out from its lurking-places on the coast, and the degree of success achieved.

Very different types of men have been named pirates. They have in fact been so unlike that to class them all together would be in the last degree unjust. The Greek in the youth of the world, and the Malay of Borneo in the 19th century, knew of no rule of morals which should restrain them from treating all who lay outside the limits of their city or their tribe as enemies, to be traded with when strong and plundered when weak. They might be patriotic, and law-abiding men towards the only authority they recognized. Their piracy was a form of war, not without close moral analogies to the seizure of Silesia by Frederick the Great, the attempted seizure of Spain by Napoleon. Indeed the story of this latter venture, with its deceitful preliminary success and its final disaster, may fairly be compared with the fall of Ulysses and his companions on the Cicones, as told in the ninth book of the *Odyssey*. Yet it would be highly uncritical to class Ulysses or Napoleon with Captain Avery, or Captain Kidd, or Bartholomew Roberts. We are not here concerned with the legal aspects of piracy, but with the true character of the persons to whom the name pirate has been applied at various times. The term was applied by the Romans to the adventurers against whom Pompey was commissioned to act by the Gabinian Law, by the English of the 9th and 10th centuries to the Vikings, and by the Spaniards to the English, French and Dutch who were found sailing beyond the line. Sufferers by naval commerce-destroyers call it "a piratical form of warfare." But the pirates of the Roman Republic were no mere "gang of robbers." They were the victims of a time of conquest and "general overture"—"the ruined men of all nations, the hunted refugees of all vanquished parties, everyone that was wretched and daring—and where was there not misery and violence in this unhappy age? It was no longer a gang of robbers who had flocked together, but a compact soldier state, in which the freemasonry of exile and of crime took the place of nationality, and within which crime redeemed itself, as it so often does in its own eyes, by displaying the most generous public spirit." Such men are akin to the *fuorusciti* of Italian history or the Dutch Beggars of the Sea, the victims of party strife in the cities, who took to the sword because they had no other resource. *Mutatis mutandis* we may say as much for the intruders beyond the line, whom history calls the "Buccaneers" (*q.v.*). The "Vikings" (*q.v.*) were a portion of the Barbarian invasions. The "Barbary Pirates" (*q.v.*) stand apart. As for the piratical character of the commerce-destroyer, or privateer—why are we to brand Captain Fortunatus Wright, the Englishman who captures a French merchant ship, or Captain Robert Surcouf, the Frenchman who captures a British East Indiaman, as piratical, and not make the same reproach against Admiral Lord Howe, or Admiral Don Luis de Córdoba, who with a fleet captures whole convoys?

The pirate pure and simple is that member of an orderly community who elects to live on the sea, by violence and robbery, making no distinction between his own city or tribe and any other. The old adage that "war makes thieves and peace hangs them" has ever been peculiarly true of the sea. War has always been conducted there by the capture of an enemy's property, and by division of the spoil. A portion of the naval forces of all nations has been composed of privateers, letters of marque or corsairs, who plundered with a licence. They have ever found a difficulty in drawing the line between enemy and neutral; when peace returned some of them found it hard to be content with honest wages earned by dull industry. Nelson declared that all privateers were no better than pirates. He was borne out by the experience of Great Britain, which at the beginning of the Seven Years' War had to take strong measures to repress the excesses of its privateers, and to hang a good few of them as mere pirates. The pirates suppressed by Pompey did not all submit to remain in the settlements he made. Some continued to rob at sea. If we can trust the *Pastoral* of Longus, and the other Greek romances, the pirate was a known type even under the Roman peace, but it is highly probable that he was more of a stock literary figure than a reality. Before the Roman peace, and during long centuries after it had been shattered, piracy was common. It grew out of a state of war. In modern times—even down to 1815—a recrudescence of piracy has followed regular hostilities. But there are other conditions which have a material influence, such as the need for a lurking-place and for a receiver of the plundered goods. An archipelago provides the best lurking-places, and next to it a coast of many inlets. Therefore the Greek Islands, the British Isles, the Antilles, the Indian Ocean, the coast of Cilicia in Asia Minor, of Dalmatia, of Malabar and of Norway, have all at one time or other, and some of them for centuries, been haunts of pirates. The convenience of the place had to be completed by the convenience of the market. In the ancient world, and the middle ages, the market never failed. One city or tribe had little care for the sufferings of another. The men of the Cinque Ports who plundered the men of Yarmouth knew that their own townsmen would never call them to account, and therefore they had a safe refuge. Even when the medieval anarchy had come to an end on land, the sea was lawless. When peace was made with Spain after the death of Queen Elizabeth there were many who could not settle down to a life of industry. Some took the

plain course of betaking themselves to Algiers or Salee. But there were many who prowled nearer home. Sir William Monson, in his *Naval Tracts*, tells how he was sent in 1605 to hunt pirates out of the Shetlands and the Hebrides. He found none at sea near Scotland, but some unemployed, whom he shipped and used as guides and informers, on the coast of Ireland. At Broad Haven he discovered an Irish gentleman of the name of Cormat (presumably Cormac) living in some dignity. His house was "the well-head of all pirates," and their captains were the lovers of his daughters. Monson found agents of merchants of London and of Galway, who came to buy the goods which the pirates had to sell at a bargain. He put that interesting family under the gallows, and frightened them into turning king's evidence. It was his boast that he had cleared the Irish coast of pirates, but we know that they were common late in the reign of Charles I., and that under the name of "sea Tories" they abounded during the Civil War both in Ireland and in the Scilly Isles. Their existence was prolonged by the weakness of the government, which when piracy became very rampant took the disastrous course of offering pardon to all who would come in by a certain date. As a matter of course many did, and when their booty was spent returned to their piratical trade. Monson says that the pirates he caused to be executed had already tasted of the king's mercy. While there were friendly harbours to anchor in, purchasers to be met and a very fair prospect of a free pardon, piracy was not likely to cease.

As the 17th century drew on the law and the police became too strong for such persons as Mr Cormat at Broad Haven, and his pirate friends. But the pirate class did not cease. It was only driven to a wider field of operations—to a field which in fact stretched from the Red Sea to New England. On this wide portion of the earth's surface everything combined to favour the pirate. In the West Indies there was a "well-head" of immense capacity. Spain was forced late and reluctantly to recognize the legitimacy of any foreign settlement. She would rather put up with the lawless adventurers known as the "Brothers of the Coast" and the "Buccaneers" than co-operate with foreign governments to suppress them. Even when she renounced her full pretensions, several of the islands remained unoccupied except by the lingering remnants of the native races. Swine and cattle had been let loose on many of them, and had multiplied. The turtle was abundant and succulent. There was no want of food. A population with predatory instincts had been formed in the early days of hostile settlement and buccaneering. Jamaica was full of the so-called "private men-of-war" whose doings are prominent in the correspondence of the early governors, who were not uncommonly their associates. Add to this that the commercial policy of Spain denied to her colonists the right of trading with foreigners, and yet that she could not supply their needs herself. Hence arose a smuggling trade which had affinities with piracy. The lawless trader was not liable to be asked awkward questions, as to the origin of his cargo, by the Spanish American who purchased it on the sly for money or by barter. Nor were any questions asked him when he brought his cargo to Jamaica, San Domingo, the Carolinas, New England or even Europe. In the decay of Spain her navy was not to be feared. But it was not the commercial policy of Spain alone which helped the pirate. Great Britain, and France also, insisted that their colonists should trade exclusively with or through them. The colonists were always ready to buy "good cheap" from the smuggler, and never ask him whether the East Indian produce —tea, silk, spices and so forth—he offered for sale were purchased or plundered in the Red Sea or on the coast of Malabar or of Coromandel. Add to all this that the police and patrol work of regular navies was but superficially done even in peace, and hardly at all in war, and that in the British colonies there was no judicial machinery for trying pirates till the 11th and 12th years of William III. (1700, 1701), and it will be seen that all the conditions favoured the pirate. In the East the decadence of the Mogul Empire was plunging India into anarchy, and it had no navy. Yet a large native trade existed, conducted by "Moors," as they were called, and Madagascar, a great "no-man's-land," afforded ample anchorage and food. To get possession of a ship, to sail to the East, to plunder the "Moors," to sell the booty in New England or the Carolinas, to spend the produce in riotous living, and go to sea on the same errand again, was the round of life of the large class of known pirates, who formed a recognized element of the population of Massachusetts and New York at the end of the 17th century. These are the men we know best, for they were encouraged by the tolerance shown them to come into the light. Others are buried in, or only dimly visible in, obscurity. Some trace of these latter may be found in the *Letter Books* of the Old Providence Company, a puritan society formed in the reign of Charles I., of which Pym and the earl of Warwick, afterwards the Parliamentary admiral of the Civil War, were governors. It was founded to colonize Old Providence on the coast of Honduras, a place not to be confused with another pirate haunt, New Providence in the Bahamas. It took to plain piracy and was suppressed by the Spaniards in 1638. Warwick made a regular business and large profits by fitting out "privateers," which were in fact pirates on the "Spanish main," not the seas of America, as some have thought, but the coast of the mainland.

The lives of the later and better known pirates may be illustrated by the career of Captain Avery, or Every (alias Bridgman), whose renown was great at the end of the 17th century, and who has the credit of having inspired Defoe's *Life, Adventures and Piracies of Captain Singleton.* Avery was mate of a Bristol ship hired by the Spaniards in 1694 to serve as a coastguard vessel in South America. She was called the "Charles II.," commanded by one Captain Gibson, and mounted 40 guns. While the "Charles II." was lying at Corunna, in company with another vessel also hired by the Spaniards, waiting for the payment of wages which was delayed, Avery persuaded part of the two crews to seize her and sail with her on a piratical voyage to the East. The enterprise was carried out without bloodshed or, apparently, coercion of those who were unwilling to go. Avery and his crew sailed to Madagascar, a regular haunt of the pirates. Many of them ended by remaining for life among the natives. The adventurers in the "Charles II.," who had already made some small prizes, English and Danish, were joined at the island by others of the same character who had come from the West Indies. From Madagascar they went to the Straits of Bab-el-Mandeb, to lie in wait for the trade from India. Several prizes were taken, and finally a large and valuable ship, belonging "to the Great Mogul and his subjects," was captured about ten miles from Surat. Avery and his crew now hastened to New England to sell their booty. The "Charles II." was disposed of as a privateer at Providence, and the pirates bought a sloop in which they sailed along the coast of the English colonies, selling their spoil, with the consent of the colonists and the connivance of the officials, who were bribed. In an evil hour for themselves they decided to come to England. The Indian governments, exasperated by the piracy practised at the expense of their subjects, were threatening reprisals on the East India Company. The Company made complaints to the government at home, and energetic measures of repression were taken. Avery himself escaped capture, but several of his men were brought to trial, condemned and executed. It is to be noted that when first tried, on the 19th of October 1696, they were acquitted. They were, however, re-tried on other counts, on the 31st of October. The charge of Lord Chief Justice Holt to the jury, and the address of Sir Charles Hedges, the admiralty judge, shows that they felt both the importance and the uncertainty of securing a verdict.

The cruise of Avery is not only a typical example of a piratical venture, but it is an important date in the history of the policing of the sea. The English government was roused to a sense of the necessity for strong measures to repress piracy. All the steps taken were not according to knowledge. The extraordinary private venture of Lord Bellamont and his associates who sent out Captain Kidd (*q.v.*), a man of piratical antecedents,

to suppress pirates in the Eastern seas, brought deserved discredit upon them. The decision taken on the advice of Burchett, the secretary of the admiralty, to offer a pardon to all who would surrender by a given date—for all piracies committed before the 30th of April to the east of the Cape of Good Hope, and the 30th of June 1699 to the west—was an error. It induced many to come in, but it also gave all pirates the hope that they would in the future be provided with similar means of escape. The establishment of admiralty courts in the East Indies and America and the despatch of warships were more effectual methods. Yet it was long before piracy was thoroughly checked; indeed the signing of the Peace of Utrecht was followed by a recrudescence of this form of crime. The privateers who swarmed in the West Indies and, as long as the war lasted, used, in the phrase of the time, to join the squadrons of war-ships "on the plundering account," could not settle down to dull industry. They leagued themselves into a species of pirate republic, with its capital at Providence in the Bahamas. In 1718 a special force had to be sent against them under Woodes Rogers, who is best remembered now for having taken Alexander Selkirk from the island of Juan Fernandez, in the course of a privateering voyage into the Pacific with the "duke" and "duchess" of Bristol. Rogers broke up the Providence settlement, and did a similar piece of service on the coast of Madagascar. Piracy did not, however, die. The Asiento (*q.v.*) Treaty having given Great Britain a monopoly of the slave trade with Spanish America, the monopolists, *i.e.* the South Sea Company and Royal African Company, were of course subject to the competition of interlopers. The interlopers were the natural friends of the pirates, who divided their activity between the Antilles and the west coast of Africa, plundering in the second, selling and re-fitting, not without further plunder, in the first. The most notorious of these freebooters was Bartholomew Roberts, who was introduced to piracy by Howel Davis. Roberts was the nearest known approach to the pirate of romance, ostentatious, brave, not without touches of generosity. He was killed in action with Captain Chaloner Ogle, of H.M.S. "Swallow," on the coast of Africa, in 1722.

As the American colonies grew more settled piracy became intolerable to them. Yet it lingered on the coast of North Carolina, where the pirates could either terrorize the scattered inhabitants, or were encouraged by dishonest officials. Here flourished the grotesque brute known as Blackbeard, Edward Teach, till he was run down and slain by Lieut. Milvain in 1718. It was noted that several of those who helped to suppress him afterwards "went a-pirating" themselves. So strong was the piratical tradition of the New World that even men of some standing fell into it. "Major" or Captain Stede Bonnet, who was condemned and executed at Charleston, South Carolina, as a pirate, in 1718, was a gentleman of some property in Barbadoes, who first ventured to sea in a ship of his own. Stede Bonnet had taken advantage of an act of grace, had come in on a proclamation, and had returned to a pirate's life. The last great explosion of piracy in the West Indies followed the peace of 1815. Here again we find the old conditions—privateers and other unsettled men, the safe lurking-place and the receiver. The refuge and the market were supplied by the Spanish colonies, which were plunged into anarchy by their revolt against Spain. The pirates were able to masquerade as "patriot" navies. The sloth and corruption of Spanish captains-general of Cuba were no less favourable to the pirates. The south coast of the island became a haunt of these villains till the British and American governments were driven to combine for their suppression. When they had been followed into their hiding-places and their vessels sunk, they took to brigandage on land, and were garrotted by the Spanish authorities in self-defence. The piracy of the Greek islands went on to later years, and the Malays were not tamed till nearly 1850. On the coast and the rivers of China piracy was and is endemic, but the sailing junk has no chance with the modern steamer. When cases of piracy have occurred in the Straits of Malacca or in the China seas, by which Europeans have been the sufferers, the crime has generally been perpetrated by men who shipped as passengers or as crew, and who surprised the vessel. The pirate has been as useful to the author of modern tales and poems as to the writers of the Greek romances. When he is seen in authentic evidence he is found to have been for the most part a pitiful rogue. His gains were but small. A share of £200 was wealth to a mere sailor, and one of £1000 wealth beyond the dreams of avarice. He rarely fought a warship if he could help it, and indeed nothing is more surprising than his readiness to surrender when the fate before him was the gallows.

AUTHORITIES.—The pirates of the ancient world are admirably dealt with in Mommsen's *History of Rome*. For the modern pirate, see Monson's "Naval Tracts" in *Churchill's Voyages*, v. 5 (London, 1744–1746), and in the edition of the Navy Record Society (1902). But the best accounts are to be found in the *State Trials*, vols. xiii., xiv., xv. (London, 1812). Captain Charles Johnson's *General History of the Pyrates* (London, 1724) must be used with caution. He no doubt learnt much from pirates who, having come in on a proclamation, were free to talk, but he cannot always be reconciled with authentic records. The *Documents relating to the Colonial History of the State of New York* (Albany, 1856–1858) contain many curious details. For the eastern seas, the *Compendious History of the Indian Wars; with an account of the Rise, Progress, Strength and Forces of Angria, the Pyrate*, &c., by Clement Downing (London, 1737) is useful. (D. H.)

PIRKE ABOTH. The penultimate tract of the fourth part of the Mishnah is the booklet of proverbs in five chapters called *Massecheth Aboth* (*tractatus patrum*), better known with a sixth chapter as *Pirke Aboth* (*capitula patrum*). For *Pirke Aboth* in English see *The Authorized Daily Prayer Book of the united Hebrew congregations of the British Empire*, with a new translation by the Rev. S. Singer. The six chapters are there appointed to be read one on each Sabbath afternoon between Passover and New Year. Formerly they were read, in places at least, on the six Sabbaths between Passover and Pentecost only. The subsections of the chapters are hereinafter numbered as in the Authorized Prayer Book.

Chapters i., ii.—The Mosaic succession has first to be established. Moses (i. 1–3) having received the Torah from Sinai, it was handed down to Joshua, the Elders (Josh. xxiv. 31), the Prophets and the men of the Great Synagogue, from one of the last of whom, Simon Justus, it was received by Antigonus of Socho. Next are named (i. 4–15), without any title, as links in the chain of tradition, five pairs of teachers, the last Hillel and Shammai, elsewhere in the Mishnah called *mundi patres* (Surenh. iv. 324). Rabban Jochanan ben Zacchai (ii. 9) "received from Hillel and Shammai." Sayings of Jochanan and his five disciples follow, and chap. ii. ends with words of their somewhat younger contemporary, Rabbi Tarphon (Τρύφων), to the effect *Ars longa vita brevis*. These sections (i. 1–15. ii. 9–21) contain the "Kern der Sammlung" (Strack). After the sayings of Shammai (i. 15) come interpolated sayings (i. 16–ii. 8) of Rabban Gamaliel I., Rabban Simeon, "Rabbi," *i.e.* R. Jehudah ha-Nasi (cent. A.D. 1–2), the traditional redactor of the Mishnah, Rabban Gamaliel II. and Hillel, which break the sequence.

Chapters iii., iv.—Maxims of numerous authorities, mostly Mishnah teachers and called Rabbis (Matt. xxii. 7 seq.; *J. E.* p. 27), not in exact chronological order.

Chapters v., vi.—Chap. v., which is *sui generis*, is presumably of later date than what precedes. Naming no teacher until the end, it combines historical, legendary and didactic elements. It touches upon the miraculous and its place in nature (v. 9). In form it is a series of numbered groups of things, from the ten creative Sayings to the triads of qualities which differentiate the disciples of Balaam and Abraham. R. Jacob ben Shimshon's commentary makes Aboth end with the saying of Jehudah ben Tema (v. 23), "Be bold as a leopard, and swift as an eagle, and fleet as a hart, and strong as a lion, to do the will of thy Father who is in heaven." Chapter vi., on *acquisitio legis*, is thought to have been added for use on the last of the six sabbaths above-mentioned (Strack, *J. E.* Ap. p. 61). In some manuscripts there are seven chapters.

Pirke Aboth serves as a primer to the student of rabbinic Judaism. For the most part in simple Hebrew, it has a few sayings in Aramaic (i. 13–ii. 7, v. 25, 26) and some adopted Greek words, as *paraclete* (iv. 13; Philo). He who would be pious should fulfil the dicta of Aboth (Baba Kam. 30a). It gives favourite aphorisms of leading Jewish teachers who flourished in or before the earliest Christian centuries, and supplies material for some interesting illustrations of the New Testament. Too heterogeneous to be represented by a few extracts, the collection

plain course of betaking themselves to Algiers or Salee. But there were many who prowled nearer home. Sir William Monson, in his *Naval Tracts*, tells how he was sent in 1605 to hunt pirates out of the Shetlands and the Hebrides. He found none at sea near Scotland, but some unemployed, whom he shipped and used as guides and informers, on the coast of Ireland. At Broad Haven he discovered an Irish gentleman of the name of Cormat (presumably Cormac) living in some dignity. His house was "the well-head of all pirates," and their captains were the lovers of his daughters. Monson found agents of merchants of London and of Galway, who came to buy the goods which the pirates had to sell at a bargain. He put that interesting family under the gallows, and frightened them into turning king's evidence. It was his boast that he had cleared the Irish coast of pirates, but we know that they were common late in the reign of Charles I., and that under the name of "sea Tories" they abounded during the Civil War both in Ireland and in the Scilly Isles. Their existence was prolonged by the weakness of the government, which when piracy became very rampant took the disastrous course of offering pardon to all who would come in by a certain date. As a matter of course many did, and when their booty was spent returned to their piratical trade. Monson says that the pirates he caused to be executed had already tasted of the king's mercy. While there were friendly harbours to anchor in, purchasers to be met and a very fair prospect of a free pardon, piracy was not likely to cease.

As the 17th century drew on the law and the police became too strong for such persons as Mr Cormat at Broad Haven, and his pirate friends. But the pirate class did not cease. It was only driven to a wider field of operations—to a field which in fact stretched from the Red Sea to New England. On this wide portion of the earth's surface everything combined to favour the pirate. In the West Indies there was a "well-head" of immense capacity. Spain was forced late and reluctantly to recognize the legitimacy of any foreign settlement. She would rather put up with the lawless adventurers known as the "Brothers of the Coast" and the "Buccaneers" than co-operate with foreign governments to suppress them. Even when she renounced her full pretensions, several of the islands remained unoccupied except by the lingering remnants of the native races. Swine and cattle had been let loose on many of them, and had multiplied. The turtle was abundant and succulent. There was no want of food. A population with predatory instincts had been formed in the early days of hostile settlement and buccaneering. Jamaica was full of the so-called "private men-of-war" whose doings are prominent in the correspondence of the early governors, who were not uncommonly their associates. Add to this that the commercial policy of Spain denied to her colonists the right of trading with foreigners, and yet that she could not supply their needs herself. Hence arose a smuggling trade which had affinities with piracy. The lawless trader was not liable to be asked awkward questions, as to the origin of his cargo, by the Spanish American who purchased it on the sly for money or by barter. Nor were any questions asked him when he brought his cargo to Jamaica, San Domingo, the Carolinas, New England or even Europe. In the decay of Spain her navy was not to be feared. But it was not the commercial policy of Spain alone which helped the pirate. Great Britain, and France also, insisted that their colonists should trade exclusively with or through them. The colonists were always ready to buy "good cheap" from the smuggler, and never ask him whether the East Indian produce —tea, silk, spices and so forth—he offered for sale were purchased or plundered in the Red Sea or on the coast of Malabar or of Coromandel. Add to all this that the police and patrol work of regular navies was but superficially done even in peace, and hardly at all in war, and that in the British colonies there was no judicial machinery for trying pirates till the 11th and 12th years of William III. (1700, 1701), and it will be seen that all the conditions favoured the pirate. In the East the decadence of the Mogul Empire was plunging India into anarchy, and it had no navy. Yet a large native trade existed, conducted by "Moors," as they were called, and Madagascar, a great "no-man's-land," afforded ample anchorage and food. To get possession of a ship, to sail to the East, to plunder the "Moors," to sell the booty in New England or the Carolinas, to spend the produce in riotous living, and go to sea on the same errand again, was the round of life of the large class of known pirates, who formed a recognized element of the population of Massachusetts and New York at the end of the 17th century. These are the men we know best, for they were encouraged by the tolerance shown them to come into the light. Others are buried in, or only dimly visible in, obscurity. Some trace of these latter may be found in the *Letter Books* of the Old Providence Company, a puritan society formed in the reign of Charles I., of which Pym and the earl of Warwick, afterwards the Parliamentary admiral of the Civil War, were governors. It was founded to colonize Old Providence on the coast of Honduras, a place not to be confused with another pirate haunt, New Providence in the Bahamas. It took to plain piracy and was suppressed by the Spaniards in 1638. Warwick made a regular business and large profits by fitting out "privateers," which were in fact pirates on the "Spanish main," not the seas of America, as some have thought, but the coast of the mainland.

The lives of the later and better known pirates may be illustrated by the career of Captain Avery, or Every (alias Bridgman), whose renown was great at the end of the 17th century, and who has the credit of having inspired Defoe's *Life, Adventures and Piracies of Captain Singleton.* Avery was mate of a Bristol ship hired by the Spaniards in 1694 to serve as a coastguard vessel in South America. She was called the "Charles II.," commanded by one Captain Gibson, and mounted 40 guns. While the "Charles II." was lying at Corunna, in company with another vessel also hired by the Spaniards, waiting for the payment of wages which was delayed, Avery persuaded part of the two crews to seize her and sail with her on a piratical voyage to the East. The enterprise was carried out without bloodshed or, apparently, coercion of those who were unwilling to go. Avery and his crew sailed to Madagascar, a regular haunt of the pirates. Many of them ended by remaining for life among the natives. The adventurers in the "Charles II.," who had already made some small prizes, English and Danish, were joined at the island by others of the same character who had come from the West Indies. From Madagascar they went to the Straits of Bab-el-Mandeb, to lie in wait for the trade from India. Several prizes were taken, and finally a large and valuable ship, belonging "to the Great Mogul and his subjects," was captured about ten miles from Surat. Avery and his crew now hastened to New England to sell their booty. The "Charles II." was disposed of as a privateer at Providence, and the pirates bought a sloop in which they sailed along the coast of the English colonies, selling their spoil, with the consent of the colonists and the connivance of the officials, who were bribed. In an evil hour for themselves they decided to come to England. The Indian governments, exasperated by the piracy practised at the expense of their subjects, were threatening reprisals on the East India Company. The Company made complaints to the government at home, and energetic measures of repression were taken. Avery himself escaped capture, but several of his men were brought to trial, condemned and executed. It is to be noted that when first tried, on the 19th of October 1696, they were acquitted. They were, however, re-tried on other counts, on the 31st of October. The charge of Lord Chief Justice Holt to the jury, and the address of Sir Charles Hedges, the admiralty judge, shows that they felt both the importance and the uncertainty of securing a verdict.

The cruise of Avery is not only a typical example of a piratical venture, but it is an important date in the history of the policing of the sea. The English government was roused to a sense of the necessity for strong measures to repress piracy. All the steps taken were not according to knowledge. The extraordinary private venture of Lord Bellamont and his associates who sent out Captain Kidd (*q.v.*), a man of piratical antecedents,

PISA, a town, archiepiscopal see and capital of a province of the same name, Tuscany, Italy, on the Arno, 7 m. from the sea [1] and 49 m. west of Florence by rail. Pop. (1881), 42,779; (1900), 61,279. It still retains its ancient walls, 6½ m. in circuit, and is defended by a citadel on the south-west. The principal streets run alongside the river, and are lined with fine buildings. Besides the cathedral, the baptistery and the famous leaning tower, the city possesses several notable churches, as the Renaissance church of the Tuscan order of St Stephen, built in 1562 from plans by Vasari; San Niccolo, with a four-storeyed tower (1230), built by Niccola Pisano, and the tomb of John of Swabia, the parricide; Santa Caterina (1262); Santa Maria della Spina, in the Italo-Gothic style, built in 1230 and restored in 1872; San Sepolchro, erected in 1150 by Diotisalvi; San Francesco, with frescoes by Taddeo Gaddi; and the basilica of San Michele (1018). Amongst the secular buildings may be mentioned the royal palace; the archiepiscopal palace; the palace of the order of St Stephen, built by Niccola Pisano and reconstructed by Vasari; the Upezzinghi (formerly Lanfreducci) palace, built of Carrara marble in 1590; the Lanfranchi, Agostini and other palaces; the university (1472); a large hospital (1258); and fine market halls. There are statues to Cosimo I. (by Francavilla), Archduke Leopold and Ferdinand I. The city possesses also an academy of the fine arts, with a gallery of paintings; and the university a library of 120,000 volumes, a natural history museum, botanical garden and agricultural schools. The university, founded in 1338, has faculties of law, medicine, mathematics and philosophy and literature, and is to this day one of the most famous in Italy.

The architects of the cathedral were Boschetto and Rinaldo, both Italians, probably Pisans. It is in plan a Latin cross, with an internal length of 311½ ft. and a breadth of 252 ft. The nave, 109 ft. high, has double vaulted aisles and the transepts single aisles; and at the intersection of nave and transepts there is a cupola. The basilica is still the predominant type, but the influence of the domed churches of Constantinople and the mosques of Palermo is also apparent. The pillars which support the nave are of marble from Elba and Giglio; those of the side aisles are the spoils of ancient Greek and Roman buildings brought by the Pisan galleys. Externally the finest part of the building is the west front, in which the note struck by the range of arches running round the base is repeated by four open arcades. Of the four doors three are by John of Bologna, who was greatly helped by Francavilla, Tacca and others; that of the south side, of much older date, is generally supposed to be the work of Bonanno. Of the interior decorations it is enough to mention the altars of the nave, said to be after designs by Michelangelo, and the mosaics in the dome and the apse, which were among the latest designs of Cimabue. The baptistery was completed only in 1278, and marred in the 14th century by the introduction of Gothic details. The building is a circle 100 ft. in diameter, and is covered with a cone-surmounted dome 190 ft. high on which stands a statue of St Ranieri. The lowest range of semicircular arches consists of twenty columns and the second of sixty; and above this is a row of eighteen windows in the same style separated by as many pilasters. In the interior, which is supported by four pilasters and eight columns, the most striking features are the octagonal font and the hexagonal pulpit, erected in 1260 by Niccola Pisano. The campanile or "leaning tower of Pisa" is a round tower, the noblest, according to Freeman, of the southern Romanesque. Though the walls at the base are 13 ft. thick, and at the top about half as much, they are constructed throughout of marble. The basement is surrounded by a range of semicircular arches supported by fifteen columns, and above this rise six arcades with thirty columns each. The eighth storey, which contains the bells, is of much smaller diameter than the rest of the tower, and has only twelve columns. The height of the tower is 179 ft., but the ascent is easy by a stair in the wall, and the visitor hardly perceives the inclination till he reaches the top and from the lower edge of the gallery looks "down" along the shaft receding to its base. The tower leans or deviates from the perpendicular, to a striking extent, which has gradually increased: it was 15¼ ft. out of the perpendicular when measured in 1829, and 16½ ft. in 1910. There is no reason to suppose that the architects, Bonanno and William of Innsbruck, intended that the campanile should be built in an oblique position; it would appear to have assumed it while the work was still in progress. The foundations are not more than 10 ft. deep, and their circumference only that of the tower. The Campo Santo, lying to the north of the cathedral, owes its origin to Archbishop Ubaldo (1188–1200), who made the spot peculiarly sacred by bringing fifty-three shiploads of earth from Mount Calvary. The building, erected in the Italian Gothic style between 1278 and 1283, by Giovanni Pisano, is of special interest chiefly for its famous frescoes.

There are numerous industries, the most important being the manufacture of cottons. In the vicinity are the royal stud-farm (horses and dromedaries) of Cascine di San Rossore, and the mineral baths of San Giuliano, alkaline-ferruginous, with temperature 91·4° to 105·8° Fahr. At the mouth of the Arno, joined to the city by a steam tramway, is the seaside resort of Marina di Pisa, also known as Bocca d'Arno, a well-known centre for landscape painters.

The old town occupied the site of the ancient Pisae on the right bank of the Arno. The foundation of Pisae is by tradition ascribed to a very remote period, and it was often (possibly only owing to the similarity of name) believed to have been founded from Pisae in Elis. It is first mentioned in history as the place at which a Roman army from Sardinia landed in 225 B.C., its harbour being at the mouth of the south branch of the Arno, north of Livorno. Being situated on the coast road (Via Aemilia) it was important as a frontier fortress against Liguria, to which, and not to Etruria, it really belonged, perhaps, up to the time of Sulla, the actual boundary lying between it and Vada Volaterrana (mod. Vada). It became a colony in 180 B.C., and was important for the fertility of its territory, for its quarries, and for the timber it yielded for ship-building. Augustus gave it the name of Colonia Julia Pisana; his grandsons Gaius and Lucius were patrons of the colony, and after their death monuments were erected in their honour, as is recorded in two long inscriptions still extant. Greek vases have been found within the city itself, seeming to point to the presence of Etruscan tombs (G. Ghirardini in *Notizie degli Scavi*, 1892, 147); but no remains now exist except of the Roman period—some scanty ruins of baths and of a temple, while the Piazza dei Cavalieri follows the outline of the ancient theatre.

See E. Bormann, *Corp. inscr. lat.* xi. 272 (1888).

Little is known of the history of Pisa during the barbarian invasions, but it is an ascertained fact that it was one of the first towns to regain its independence. Under the Byzantine dominion Pisa, like many other of the maritime cities of Italy, profited by the weakness of the government at Constantinople to reassert its strength. And even during the first years of the harsh Lombard rule the need recognized by these oppressors of defending the Italian coast from the attacks of the Byzantines was favourable to the development of the Pisan navy. Few particulars are extant concerning the real condition of the town; but we occasionally find Pisa mentioned, almost as though it were an independent city, at moments when Italy was overwhelmed by the greatest calamities. According to Amari's happy expression, "it was already independent by sea, while still enslaved on land." Its prosperity notably declined after the establishment of the Lombard rule and under the Franks. It again began to flourish under the marquises of Tuscany, who governed it in the name of the emperor.

In 1003 we find records of a war between Pisa and Lucca, which, according to Muratori, was the first waged between Italian cities in the middle ages. But the military development and real importance of Pisa in the 11th century must be attributed to the continuous and desperate struggle it maintained against the tide of Saracenic invasion from Sicily. And, although the numerous legends and fables of the old chroniclers disguise the true history of this struggle, they serve to attest the importance of Pisa in those days. In 1004 the Saracens forced the gates and sacked a quarter of the town; and in 1011 they renewed the attack. But the Pisans repulsed them and assumed the offensive in Calabria, Sicily, and even in Africa. Still more memorable was the expedition afterwards undertaken by the united forces of Pisa and Genoa against Mogahid, better known in the Italian chronicles as Mugeto. This Moslem chief had made himself master of Sardinia, and was driven thence by the allied fleets in 1015. Again invading the island, he was again attacked and defeated by the same adversaries, leaving a

[1] In Strabo's time it was only 2 m. away, but the increase of the delta at the mouth of the river has since then pushed forward the coast-line.

brother and son, or, as some authorities aver, a wife and son, prisoners in their hands. Sardinia continued to be governed by native "judges" who were like petty sovereigns, but were now subject to the sway of Pisa. This was the primary cause of the jealousy of the Genoese, and of the wars afterwards made by them upon Pisa and carried on until its power was crushed. Meanwhile the Pisans flourished more and more, and continued hostilities against the Saracens. In 1062 their ships returned from Palermo laden with spoil. Thus it is not surprising that Pisa should already have had its own code of laws (*Consuetudini di mare*), which in 1075 were approved by Gregory VII., and in 1081 confirmed by a patent from the emperor Henry IV., a document which mentions for the first time the existence of a magistrate analogous to the consuls of the republic, although the latter, according to some writers, already existed in Pisa as early as the year 1080; the point, however, is doubtful, and other writers place the first authentic mention of the consuls in the year 1094.[1] The oldest of Pisan statutes still extant is the *Breve dei consoli di mare* of 1162.

In 1099 the Pisans joined in the second crusade, proved their valour at the capture of Jerusalem, and derived many commercial advantages from it; for within a short time they had banks, consuls, warehouses and privileges of all kinds in every Eastern port. Thus, while the commune of Pisa was still under the rule of the marquises of Tuscany, all negotiations with it were carried on as with an independent state officially represented by the archbishop and consuls. The aristocrats were the dominant party, and filled the highest offices of the republic, which, in the 12th century, rose to great power, both on sea and land, by its wars with the Lucchese, Genoese and Moslems. In 1110 Pisa made peace with Lucca after six years of continuous hostilities. And in the years 1113 and 1115 it achieved a still greater enterprise. The Pisan fleet of three hundred sail, commanded by the archbishop Pietro Moriconi, attacked the Balearic Isles, where as many as 20,000 Christians were said to be held captive by the Moslems, and returned loaded with spoil and with a multitude of Christian and Moslem prisoners. The former were set at liberty or ransomed, and among the latter was the last descendant of the reigning dynasty. The chief eunuch who had governed Majorca perished in the siege. Immediately afterwards the Fourteen Years' War with Genoa broke out. The two republics contested the dominion of the sea, and both claimed supreme power over the islands of Corsica and Sardinia. A papal edict awarding the supremacy of Corsica to the Pisan church proved sufficient cause for the war, which went on from 1118 to 1132. Then Innocent II. transferred the supremacy over part of Corsica to the Genoese church, and compensated Pisa by grants in Sardinia and elsewhere. Accordingly, to gratify the pope and the emperor Lothair II., the Pisans entered the Neapolitan territory to combat the Normans. They aided in the vigorous defence of the city of Naples, and twice attacked and pillaged Amalfi, in 1135 and 1137, with such effect that the town never regained its prosperity. It has been said that the copy of the Pandects then taken by the Pisans from Amalfi was the first known to them, but in fact they were already acquainted with those laws. The war with Genoa never came to a real end. Even after the retaking of Jerusalem by the Moslems (1187) the Pisans and Genoese again met in conflict in the East, and performed many deeds of valour. They were always ready to come to blows, and gave still more signal proofs of their enmity during the Sicilian War in behalf of the emperor Henry VI. From that moment it was plain that there could be no lasting peace between these rival powers until the one or the other should be crushed. The greatness and wealth of the Pisans at this period of their history is proved by the erection of the noble buildings by which their city is adorned. The foundations of the cathedral were laid in 1063, and its consecration took place in 1118; the baptistery was begun in 1152, and the campanile (the famous leaning tower) in 1174. And all three magnificent structures were mainly the work of Pisan artists, who gave new life to Italian architecture, as they afterwards renewed the art of sculpture.

It is asserted by some writers, especially by Tronci, that in the 12th century Pisa adopted a more democratic form of government. But in fact the chief authority was still vested in the nobles, who, both in Pisa and in Sardinia, exercised almost sovereign power. They formed the real strength of the republic, and kept it faithful to the empire and the Ghibelline party. The Guelph and popular element which constituted the force and prosperity of Florence was hostile to Pisa, and led to its downfall. The independence of the former city was of much later origin, only dating from the death of Countess Matilda (1115), but it rapidly rose to an ever-increasing power, and to inevitable rivalry with Pisa. Owing to the political and commercial interests binding Florence to the Roman court, the Guelph element naturally prevailed there, while the growth of its trade and commerce necessarily compelled that state to encroach on waters subject to Pisan rule. And, although Pisa had hitherto been able to oppose a glorious resistance to Genoa and Lucca, it was not so easy to continue the struggle when its enemies were backed by the arms and political wisdom of the Florentines, who were skilled in obtaining powerful allies. The chroniclers ascribe the first war with Florence, which broke out in 1222, to a most ridiculous motive. The ambassadors of the rival states in Rome are said to have quarrelled about a lapdog. This merely shows that there were already so many general and permanent reasons for war that no special cause was needed to provoke it. In 1228 the Pisans met and defeated the united forces of Florence and Lucca near Barga in the Garfagnana, and at the same time they despatched fifty-two galleys to assist Frederick II. in his expedition to the East. Shortly after this they renewed hostilities with the Genoese on account of Sardinia. The judges who governed the island were always at strife, and, as some of them applied to Pisa and some to Genoa for assistance against one another, the Italian seas were once more stained with blood, and the war burst out again and again, down to 1259, when it terminated in the decisive victory of the Pisans and the consolidation of their supremacy in Sardinia. But meanwhile Florence had made alliance with Genoa, Lucca and all the Guelph cities of Tuscany against its Ghibelline rival. The pope had excommunicated Frederick II. and all his adherents. And, as a crowning disaster, the death of Frederick in 1250 proved a mortal blow to the Italian Ghibelline cause. Nevertheless, the Pisans were undaunted. Summoning Siena, Pistoia and the Florentine exiles to their aid, they boldly faced their foe, but were defeated in 1254. Soon after this date we find the old aristocratic government of Pisa replaced by a more popular form. Instead of the consuls there were now twelve elders (*anziani*); besides the podestà, there was a captain of the people; and there was a general council as well as a senate of forty members. The rout of the Tuscan Guelphs on the field of Montaperto (1260) restored the fortunes of Pisa. But the battle of Benevento (1266), where Manfred fell, and the rout of Tagliacozzo (1268), sealing the ruin of the house of Hohenstaufen in Italy and the triumph of that of Anjou, were fatal to Pisa. For the republic had always sided with the empire and favoured Conradin, whose cruel end struck terror into the Ghibelline faction. The pope hurled an edict against the Pisans and tried to deprive them of Sardinia, while their merchants were driven from Sicily by the Angevins. The internal condition of the city was affected by these events. Owing to the increasing influence of the Guelph and popular side, to which the more ambitious nobles began to adhere for the furtherance of personal aims, the aristocratic Ghibelline party was rapidly losing ground. The first man to step to the front at this moment was Count Ugolino della Gherardesca of the powerful house of that name. He had become the virtual head of the republic, and, in order to preserve its independence and his own sway, inclined to the

[1] It must be remembered that the Pisans and Florentines dated the beginning of the year *ab incarnatione*, *i.e.* from the 25th of March. But the Florentines dated it from the 25th following and the Pisans from the 25th of March preceding the commencement of the common year. The new or common style was adopted throughout Tuscany in the year 1750.

Guelphs and the popular party, in spite of the Ghibelline traditions of his race. He was supported by his kinsman Giovanni Visconti, judge of Gallura; but almost all the other great families vowed eternal hatred against him, and proclaimed him a traitor to his party, his country and his kin. So in 1274 he and Visconti were driven into exile. Both then joined the Florentines, took part in the war against their native city, and laid waste its surrounding territories. In 1276 the Pisans were compelled to agree to very grievous terms—to exempt Florentine merchandise from all harbour dues, to yield certain strongholds to Lucca, and to permit the return of Count Ugolino, whose houses they had burnt, and whose lands they had confiscated. Thus the count again became a powerful leader in Pisa. Visconti, however, was dead.

This was the moment chosen by Genoa for a desperate and decisive struggle with her perpetual rival. For some years the hostile fleets continued to harass each other and engage in petty skirmishes, as if to measure their strength and prepare for a final effort. On the 6th of August 1284 the great battle of Meloria took place. Here seventy-two Pisan galleys engaged eighty-eight Genoese, and half the Pisan fleet was destroyed. The chroniclers speak of 5000 killed and 11,000 prisoners; and, although these figures must be exaggerated, so great was the number of captives taken by the Genoese as to give rise to the saying—"To see Pisa, you must now go to Genoa." This defeat crushed the power of Pisa. She had lost her dominion over the sea, and the Tuscan Guelphs again joined in attacking her by land. Count Ugolino had taken part in the battle of Meloria and was accused of treachery. At the height of his country's disasters he sought to confirm his own power by making terms with the Florentines, by yielding certain castles to Lucca, and by neglecting to conclude negotiations with the Genoese for the release of the prisoners, lest these should all prove more or less hostile to himself. This excited a storm of opposition against him. The archbishop Ruggieri, having put himself at the head of the nobles, was elected podestà by the Lanfranchi, Sismondi and Gualandi, and a section of the popular party. The city was plunged into civil war. The great bell of the commune called together the adherents of the archbishop; the bell of the people summoned the partisans of the count. After a day's fighting (July 1, 1288) the count, his two sons and his two grandsons were captured in the palazzo del popolo (or town hall), and cast into a tower belonging to the Gualandi and known as the "Tower of the Seven Streets." Here they were all left to die of hunger. Their tragic end was afterwards immortalized in the *Divina Commedia*. The sympathies of Dante Alighieri, the Florentine patriot and foe of Rome, were naturally in favour of the victims of an aristocratic prelate, opposed to all reconciliation with Florence.

The Florentines were now allied with Lucca and Genoa, and a few of their vessels succeeded in forcing an entry into the Pisan port, blocked it with sunken boats, and seized its towers. Their own internal dissensions of 1293 put a stop to the campaign, but not before they had concluded an advantageous peace. They and all the members of the Guelph League were freed from all imposts in Pisa and its port. In addition to these privileges the Genoese also held Corsica and part of Sardinia; and throughout the island of Elba they were exempted from every tax. They likewise received a ransom of 160,000 lire for their Pisan prisoners. These were no longer numerous, many having succumbed to the hardships and sufferings of all kinds to which they had been exposed.

In 1312 the arrival of the emperor Henry VII. gladdened the hearts of the Pisans, but his sudden death in 1313 again overthrew their hopes. He was interred at Pisa, and Uguccione della Faggiuola remained as imperial lieutenant, was elected podestà and captain of the people, and thus became virtual lord of the city. As a Ghibelline chief of valour and renown he was able to restore the military prestige of the Pisans, who under his command captured Lucca and defeated the Florentines at Montecatini on the 29th of August 1315. So tyrannical, however, was his rule that in 1316 he was expelled by the popular fury. But Pisa's freedom was for ever lost. He was succeeded by other lords or tyrants, of whom the most renowned was Castruccio Castracane, a political and military adventurer of much the same stamp as Uguccione himself. With the help of Louis the Bavarian, Castruccio became lord of Lucca and Pisa, and was victorious over the Florentines; but his premature death in 1328 again left the city a prey to the conflicts of opposing factions. New lords, or petty tyrants, rose to power in turn during this period of civil discord, but the military valour of the Pisans was not yet extinguished. By sea they were almost impotent—Corsica and Sardinia were lost to them for ever; but they were still formidable by land. In 1341 they besieged Lucca in order to prevent the entry of the Florentines, to whom the city had been sold for 250,000 florins by the powerful Mastino della Scala. Aided by their Milanese, Mantuan and Paduan allies, they gave battle to their rivals, put them to rout at Altopascio (Oct. 2), and then again excluded them from their port. Thereupon the Florentines obtained Porto Talamone from Siena and established a navy of their own. By this means they were enabled to capture the island of Giglio, and, attacking the Pisan harbour, carried off its chains, bore them in triumph to Florence, and suspended them in front of the baptistery, where they remained until 1848. Then, in pledge of the brotherhood of all Italian cities, they were given back to Pisa, and placed in the Campo Santo.

The war was now carried on by the free companies with varying fortune, but always more or less to the hurt of the Pisans. In 1369 Lucca was taken from them by the emperor Charles IV.; and afterwards Giovan Galeazzo Visconti, known as the count of Virtù, determined to forward his ambitious designs upon the whole of Italy by wresting Pisa from the Gambacorti. For at this time the conflicts of the Raspanti faction, headed by the Gherardesca, with the Bergolini led by the Gambacorti, had left the latter family masters of the city. At Visconti's instigation Piero Gambacorti, the ruler of the moment, was treacherously assassinated by Jacopo d'Appiano, who succeeded him as tyrant of Pisa, and bequeathed the state to his son Gherardo. The latter, a man of inferior ability and daring, sold Pisa to the count of Virtù, receiving in exchange 200,000 florins, Piombino, and the islands of Elba, Pianosa and Monte Cristo. Thus in 1399 Visconti took possession of Pisa, and left it to his natural son Gabriele Maria Visconti, who was afterwards expelled from its gates. But even during this century of disaster the Pisans continued to cherish not only commerce, but also the fine arts. In the year 1278 they had entrusted the erection of their fine Campo Santo to Niccola and Giovanni Pisano, by whom the architectural part of it was completed towards the end of the century. In the following year the first artists of Italy were engaged in its decoration, and the celebrated frescoes attributed to Orcagna (*q.v.*) were painted on its walls. Others were afterwards supplied by Benozzo Gozzoli and men of lesser note, and the labour of ornamentation was only discontinued in 1464.

Meanwhile, in 1406, the Florentines made another attack upon Pisa, besieging it simultaneously by sea and land. Owing to the starving condition of its defenders, and aided by the treachery of Giovanni Gambacorti, they entered the city in triumph on the 9th of October, and sought to "crush every germ of rebellion and drive out its citizens by measures of the utmost harshness and cruelty." Such were the orders sent by the Ten of War to the representatives of the Florentine government in Pisa, and such was then the established policy of every Italian state. Consequently for a long time there was a continual stream of emigration from Pisa. The Medici pursued a humaner course. In 1472 Lorenzo the Magnificent tried to restore the ancient renown of the Pisan university. To that end he filled it with celebrated scholars, and, leaving only a few chairs of letters and philosophy in Florence, compelled the Florentines to resort to Pisa for the prosecution of their studies. But nothing could now allay the inextinguishable hatred of the conquered people. When Charles VIII. made his descent into Italy in 1494, and came to Sarzana on his way to Tuscany, he was welcomed by the Pisans with the greatest demonstrations of joy. And, although that monarch was ostensibly the friend of Florence, they did not
